diet, the oxidation of this excess interfering with the oxidation of the more complex protein molecule; (4) that the toxæmia is manifest first as catarrh, later as spasm in the respiratory tract; (5) that the nose is an important factor both in the origin and in the course of the disease; (6) that owing to the prolonged toxæmia there is nervous hyperexcitability, affecting especially the vagus. He supported these views by reference to the fact that 42 per cent. of his cases occurred in the first decade—the age of dietetic and hygienic errors, and, moreover, the age of the "immunity struggle" against the infections prevalent in that decade; by the cures effected on asthmatics by active service during the war; by the absence of asthma among races who had to hunt for their food; by researches carried out by himself and others on animals attacked by a similar disorder; by the week-end incidence of a large body of cases; by the therapeutic test, which showed 70 per cent. recoveries under a very simple régime. From a series of blood and urine analyses he showed a relatively low urea value as compared with non-protein nitrogen in asthmatic bloods, a low urea value to total nitrogen in asthmatic urines. He held that the modern confusion between asthma and anaphylaxis arose from a misconception of what anaphylaxis really was. A sensitizing dose of protein introduced otherwise than by the alimentary canal produced a profound though not apparent change, so that, after an interval, a second dose resulted in illness, and often death. The most striking effect in a general affection of the tissues was on smooth muscle, and the organ most affected was that where the muscle was most strongly developed. Anaphylactic phenomena might appear in asthmatics in whom the muscles of the bronchioles were hypertrophied by prior toxæmia and spasm. This term had, however, been unwarrantably extended. It had been loosely applied to include all idiosyncrasies to food or non-protein drugs, even on their first introduction. "Allergy" was the word used for these reactions, and the protein skin reaction had been introduced to test for their presence. Fifty per cent. positive results had been claimed by Coke and others. Dr. Adam considered that 50 per cent. failures proved something simpler and more radical than anaphylaxis in asthma, even in many of the positive cases. In his own series, including hay fever, which was not asthma, he had 40 per cent. positive results, and he did not put 40 per cent. emphasis on them. He summed up by saying that asthma was in reality a symptom producible (1) slowly by toxæmia and commonly as one of a chain of respiratory symptoms, (2) suddenly by special toxæmia or anaphylaxis, or (3) suddenly by strong nasal irritation. As regarded treatment, the main principles were to secure a state of general well-being, and to see that the nose was right. He gave a short account of his own operative and dietetic procedure.

Dr. IVY McKENZIE considered that Dr. Adam's theories might yet be found to fit into the whole scheme of metabolic perversion. He thought the eugestive prodromata of asthma, as represented by nasal catarrh, enlarged turbinates, and laryngitis, might be due to a central poisoning of the roots of the nerves in the medulla. In connexion with the vagal element in asthma, he had found that a dose of apomorphine sufficient to produce vomiting would abort an attack of asthma. He concurred in the attack on the "anaphylactists."

Dr. KEAR LOVE was sceptical of the value of the protein tests. He recalled a case strongly positive to pork to whom he at once administered three pork chops with no asthma. He thought Dr. Adam's work a great contribution to preventive medicine.

Dr. W. HERBERT BROWN referred to the food factor in cases of urticaria and eczema in infants. He was struck by the preponderance of the dispensary patients over private patients in this type of disorder, and considered dietetic and environmental disparity a reason for this.

Dr. J. L. HOWIE declared himself a disciple of Dr. Adam, and spoke to the value of his principles in general and in throat and nose work. Drs. CASPIE, FRASER, DAVIDSON, and REGINALD DUNLOP also took part in the discussion.

## Reviews.

### BILLROTH'S "MEDICINE" IN GERMAN UNIVERSITIES.

THAT THEODORE BILLROTH'S famous work, *Lehren und Lernen der Medicinischen Wissenschaften* has not hitherto been translated into English is remarkable, but it is even more surprising how applicable what he wrote nearly fifty years ago is to the present-day problems of medical education. *The Medical Sciences in the German Universities*,<sup>1</sup> with its subtitle *A Study in the History of Civilization*, has now been admirably translated into present-day English terms, and has the further advantage of an introduction by Professor W. H. WELCH, who pleasantly outlines the grandeur, wide sympathies, and literary talent of the Vienna surgeon, and mentions that the plain-spoken truths about the conditions in the university aroused considerable resentment, attended even by racial and riotous disturbances, in Vienna. The work is divided into four parts, dealing with (1) the development of the faculties of medicine at the German universities; (2) the present (1870) German method of teaching the medical sciences; (3) the student and the future physician; and (4) the teaching staff.

In tracing the history of clinical instruction, Billroth sketches the formerly subordinate position of surgery, which did not obtain an independent position till the seventeenth or eighteenth century, and it is now scarcely credible that the great Albrecht von Haller lectured at Berne for many years without ever having touched a human body with a knife. The qualifications of a surgeon are graphically expressed in the sentence, "A man who has not been an assistant in a surgical ward and has not performed the typical operations dozens of times on the cadaver, until he can do them as well in his sleep as when fully awake, will never be an operator." It is, of course, interesting to compare the methods of teaching in the German schools of medicine in Billroth's time with our own; even then the systematic lecture was becoming obsolete, and on this tendency he utters some words of warning which are not without their application at the present day. Speaking of the introductory portions of lectures, he remarks that the modern youth likes them as little as the public does the long overtures of modern operas. One of the few places in which his views depart from the general atmosphere of modernity is where he says that physiology is now at its high-water mark and that a professor of medical chemistry is not absolutely necessary at every university. On the other hand, he advocates courses in dietetics and balneology in every university—a piece of advice that certainly has not borne universal fruit. The problem of the State versus university qualification in medicine is discussed at length, and the shortage of rural practitioners noted; in areas where poverty makes it necessary, the doctor, like the clergyman, should, he thought, be provided with a house, and be guaranteed a certain amount for his services.

The effective teachers are divided into (1) those with the formal talent for presenting their subjects systematically to average students and are good conductors if not live wires; though there are exceptions, they tend to become petrified after fifteen years; (2) the founders of schools and the really great leaders are always of a somewhat visionary and highly imaginative nature, and not infrequently artistic, or musicians or poets. Although for their pupils these gifted men have a wonderful attraction, the personal fascination of such intellectual giants may be relatively short-lived unless their investigations are made known in the written word. Of the two categories, the efficient systematic teacher and the genius, Billroth obviously prefers the latter.

This is an attractively written book on a subject of absorbing interest, and its reappearance appropriately coincides with Mr. Abraham Flexner's survey of *Medical Education during the last fifteen years in Europe and*

America, also published by the Macmillan Company. The two should be read and assimilated by all interested in medical education.

### THE EXAMINATION OF THE EYE.

METHODICAL examination is the essence of all good clinical work in every department of medicine or surgery. In no other region of the body can so much be seen, if it be looked for, as in the eye. How easy it is to overlook important details is well known by all ophthalmic surgeons. It cannot be too often, or too strongly, impressed upon the student that only by methodical routine examination are we in a position to form a just estimate of the condition of the eye. It may not be possible to account for all we see, but the student, or surgeon for that matter, who conscientiously carries out his routine examination of a case may feel that he has done his duty by his patient even if the interpretation of the details he has found be obscure.

Mr. BASIL LANG, in his book on the *Routine Examination of the Eye*,<sup>2</sup> describes a single manner of carrying out each part of the examination of the eye. As he says in his preface, it may not be the only way, it may not, in the opinion of some, be the best way, but it is a perfectly satisfactory way, and enables the observer to obtain the desired information. With this we cordially agree; the student will find in this book an absolutely safe guide to the examination of the eye. It is clearly written and well illustrated.

Those of our readers who have had the advantage of being trained by the author's father will read the book with pleasure and will recall to memory Mr. William Lang's *Methodical Examination of the Eye*, a book which was the ophthalmological bible of their junior days, in that it pointed out most clearly the narrow track that led to ophthalmic salvation. We assume that this work is no longer in print, and we are glad indeed that the son has written this little new textbook on the same subject for the benefit of those who "knew not Joseph." Mr. William Lang's book was labelled Part 1; all who worked in his clinic at Moorfields or the Middlesex Hospital looked forward to the publication of the remaining part or parts; but none ever appeared. We sincerely hope that Mr. Basil Lang will find time to complete the idea of his father.

### STEINACH'S OPERATION.

PROFESSOR STEINACH of Vienna found that, after tying the vasa deferentia in old rats, the animals appeared to take a new lease of life; they put on fat and became agile and sexually potent. This result was attributed to an increase in the number of interstitial cells after the operation. It is claimed that a similar rejuvenescence follows vasoligation in man, and Dr. PETER SCHMIDT, in his book which, in the English version, bears the title *Theory and Practice of the Steinach Operation*,<sup>3</sup> has attempted to substantiate the claim by recording the results of eighty-four cases in which he performed the operation.

The interpretation of the results in man is complicated by the difficulty of eliminating the factor of suggestion and by the absence of any satisfactory measure of the degree of rejuvenescence obtained. Conclusions are based on a general impression of the effects, and will naturally vary in different observers. Thus very marked rejuvenescence is said to have occurred in Case 3, an innkeeper, aged 62, who was accustomed to drink brandy by the bottle, who was incapable of carrying on his business, was suffering from aortic valvular disease, purulent bronchitis, old pulmonary tubercle, gall stones, severe fibrosis of the kidneys, enlarged prostate with cystitis, and severe generalized arterial disease, causing death from apoplexy four months after the operation. Many would doubtless attribute this result to the imagination rather than to the inter-

<sup>1</sup> *The Medical Sciences in the German Universities: a Study in the History of Civilization*. Translated from the German of Theodore Billroth, with an introduction by William H. Welch. New York: The Macmillan Company, 1924. (Rc.) 8vo, pp. xiv + 222. 15s. net.)

<sup>2</sup> *The Routine Examination of the Eye*. By Basil Lang, F.R.C.S. Eng. London: E. Arnold and Co. 1925. (Cr. 8vo, pp. 155; 30 figures. 6s. net.)

<sup>3</sup> *The Theory and Practice of the Steinach Operation*. With a report on one hundred cases by Dr. Peter Schmidt (Berlin), and an introduction to the English edition by J. Johnson Abraham, C.B.E., D.S.O., M.A., M.D. Dub., F.R.C.S. Eng. London: W. Heinemann (Medical Books), Ltd. 1924. (Cr. 8vo, pp. xiv + 150; 3 diagrams. 7s. 6d. net.)

stitial cells of the testis. In other instances recorded there is no room for doubt as to the existence of mental abnormality, as in the case of the guard, aged 32, who was afflicted with the distressing impulse to press against women in the street and produce an ejaculation if possible. A case of this kind bears very little analogy to the effects of vasoligation in rats. Further, in some of the cases it is difficult to avoid the suspicion that the patients were making fun of the doctor, as in Case 76, a veterinary surgeon, aged 57. In the first weeks after the operation the condition is stated by the author to have been remarkable: the patient has "exquisite fancies; walks again as straight as a soldier; runs upstairs as actively as one does after a pleasure trip; and, at night, has erotic dreams pretty regularly."

Steinach's operations on rats suggest that man might possibly derive some benefit from vasoligation, but the suggestion is very much weakened by a perusal of Dr. Schmidt's work.

### ANAESTHESIA AND ANAESTHETICS.

In the second edition of his book *Anæsthesia*,<sup>4</sup> Dr. J. T. GWATHMEY has introduced a few alterations. He has omitted the chapters formerly devoted to electrical and sequestration anaesthesia, to mental influence and hypnosis, and to statistics; the list of anaesthetics has also been left out. Special chapters have been written by collaborators who are authorities in their respective fields of work.

The book is divided into twenty-two chapters and has two appendices. It opens with the history of anaesthesia, which is most interestingly set forth, and then the general physiology of inhalation anaesthesia is discussed very fully and adequately. Before passing on to the various anaesthetics in general use, the author discusses the use of re-breathing in the administration of anaesthetics, and points out its advantages and disadvantages. Nitrous oxide, ether, ethyl chloride, and chloroform are then each dealt with fully, after which the selection of anaesthetics and the technique for special operations are discussed. Other chapters are devoted to treatment before, during, and after anaesthesia, to anaesthesia by intratracheal insufflation, to anaesthesia by colonic absorption of ether vapour, and to local anaesthesia. Third-stage anaesthesia is discussed in a separate chapter, while local anaesthesia as applied in dentistry is also given a chapter to itself. Spinal anaesthesia is treated at very great length—in fact, as many pages are devoted to this method as to local anaesthesia. Intravenous and synergistic anaesthesia, the therapeutic uses of inhalation anaesthetics, the medico-legal status of the anaesthetist, ethylene anaesthesia, and painless childbirth by synergistic methods, each receives attention in a separate chapter. The appendices are devoted to oxygen and to the doses suitable for animals respectively. The author has produced a very valuable work, which will be welcome to British anaesthetists as showing the apparatus and methods employed in America. As a book of reference the work is also of very great value, as the author quotes chapter and verse for all his statements, and has no hesitation in stating the opinions of other authorities where they happen to differ from his own. This absence of dogmatic statement, while of use to the expert, is, perhaps, a disadvantage to the student, who is apt to be confused by a multiplicity of opinions, methods, and apparatus. Consequently the book is not one to be recommended to the British student as a first book to be read, more especially as he will not be familiar with the apparatus figured, and such apparatus as he is likely to use does not appear in the illustrations. Where the whole book is so excellent, both as to subject-matter and illustrations, it is difficult to formulate criticisms. It is perhaps allowable, nevertheless, to question whether such a large subject as local anaesthesia had not better have been dealt with in a volume by itself. This comparatively new and rapidly growing branch of the science and art of anaesthesia can hardly receive the attention it deserves in a chapter of some sixty pages, well as has the collaborator done

his work. Explanations have necessarily to be cut down to a minimum, and clearness is liable to be sacrificed to verbal economy. The mere presentation of diagrams, however excellent, is not of itself sufficient to compensate for extreme restriction of the explanatory matter. Altogether, however, this new edition enhances the author's already great reputation as a scientific anaesthetist and an authority on his art.

### EARLY CHEMISTRY.

THE author of *The Story of Early Chemistry*<sup>5</sup> has undertaken a great task. The history of chemistry contains matter of no less interest than the histories of men and empires. History proper is a woven fabric; the fabric cannot be woven until the facts have been collected for the master weaver. Only a chemist could write the history of chemistry, but the vocation offers its votaries little freedom for the pursuit of any literary inclination with which they may be endowed. Hence the perfect history, which we still await, can only grow out of the labours of the annotator of chemical records, and his notes must then be handled by one possessed of no little literary skill. These remarks are not intended to depreciate the value of STILLMAN's book, but it partakes more of the character of annotation than of constructed history. He might, indeed, have become the historian we desire had he had more time to devote to writing, for there are many pages in which the historian's gift is evident. Clearly the vast extent of ground he attempted to cover in the time at his disposal precluded a free exercise of the historian's art. The book describes what is known of chemical arts regularly practised by the ancients. It throws much light on the confusion from which the experimental efforts of the alchemists suffered; at one time they worked with different substances bearing the same name, and at another with the same substance presented under different names. This confusion goes some way to explain the mystical conceptions that surrounded their strange theories and beliefs. Between the Middle Ages and the eighteenth century there was a transition period, during which realities contended with imposture. Then came the phlogiston theory; it served as the focus of chemical thought, and had the effect of co-ordinating for the first time experimental researches of diverse kinds. Finally, the phlogiston theory, having served its day, yielded place to the foundations of modern chemistry. The dominant impression left by a perusal of Stillman's work is of the extraordinary amount of labour that must have gone to the acquisition of his materials. The book seems to be a compendium of all that has been written on chemical beliefs and on actual achievements in early chemistry. It is provided with a good index and an ample bibliography. It will not only be read for its archaeological interest, but will serve as a useful book of reference.

### HEALTH AND PERSONALITY.

DR. JOHN S. GRIFFITHS has contributed a volume to the Library of Philosophy and Religion series, entitled *Health and Personality*.<sup>6</sup> The author approaches his subject by dealing in successive chapters with the various biological stages of individual development; commencing with infancy and childhood, he ends up with the "later years," which, as he observes, can be the best period of life since they give what was missing in former stages—serenity, gentleness towards others, tolerance towards all, and the peace of life's twilight. The book is written in an easy, discursive style, and the subject-matter includes not only much excellent advice on health, but observations on life in general, and on a variety of topics such as tropisms, conditioned reflexes, eugenics, endocrines, philosophy, religion, manners, friendship, suggestion, psycho-analysis, occultism, recreations, and house furnishing. Throughout his book

<sup>4</sup> *Anæsthesia*. By James Tayloe Gwathmey, M.D. Second revised edition. London: J. and A. Churchill. 1924. (Med. 8vo, pp. xxi + 793; 273 figures. 55s. net.)

<sup>5</sup> *The Story of Early Chemistry*. By John Maxson Stillman. New York and London: D. Appleton and Co. 1924. (Demy 8vo, pp. xiii + 555. 18s. net.)

<sup>6</sup> *Health and Personality*. By John S. Griffiths, M.R.C.S., L.R.C.P., D.L. Library of Philosophy and Religion. London: Hodder and Stoughton, Ltd. 1924. (Cr. 8vo, pp. 320. 6s. net.)

the author emphasizes his views by a number of apt quotations.

Dr. Griffiths makes no attempt to write profoundly; the book is simple and readable, and we have no doubt that the ordinary layman will find it helpful and interesting. The medical practitioner, also, will probably not feel that he has wasted his time if he dips into its pages.

### NOTES ON BOOKS.

THE third edition of Dr. J. B. HURRY'S book on *Vicious Circles in Disease* has been translated into Spanish, and several new chapters have been added; a coloured front-piece illustrates the "circular process" in medicine. We published reviews of the third English edition on September 13th, 1919 (p. 346), and of the French translation of this edition on March 1st, 1924 (p. 387).

Professor WILLIS BANDLER'S *Medical Gynecology* has reached a fourth edition; in its preparation the author has had the assistance of several colleagues. Dr. W. T. Dannreuther has contributed chapters on urinary conditions and written most of the section on radium and x-ray therapy; Dr. George Mannheimer has rewritten the chapter on constipation; while Dr. Walter Highman has added the chapter on syphilis. Professor Bandler has rewritten the section on the endocrine glands, in regard to which he is a great enthusiast and no mean authority. Modern advances in psychological medicine, which are of great importance in medical gynecology, receive suitable attention. Whatever may be the reader's opinion of the propriety or value of attempting to separate medical gynecology from surgical gynecology, there can be no doubt that this book contains much in regard to minor methods of treatment which will be of value to the practitioner. These additions cannot be properly considered in their own right, but their consideration on a detailed scale would tend to overload the ordinary textbook of gynecology, and this may be the justification for a second volume. The gynecological surgeon will be the first to appreciate the valuable results which follow prolonged and painstaking adoption of some of the minor methods of treatment. The practitioner will also find great help in this book, as it explains in detail the various minor methods which can quite well be employed in a consulting room or in the patient's own home.

*Los Círculos Viciosos en Patología.* Por el Dr. Jameson B. Hurry. Traducción española, corregida y aumentada, de la 3ª edición inglesa por el Dr. Diego Moxó y Queri, con un prólogo del Dr. Augusto Pi Suñer, a Marañón Roig. 1925. (Roy. 8vo, pp. xv+338; 4s.)

Samuel Willis Bandler, M.D. Fourth Philadelphia and London: W. B. Saunders Company. 1924. (Sup. roy. 8vo, pp. 930; 157 figures. 40s. net.)

### PREPARATIONS AND APPLIANCES.

#### *Glazings Transparent to Ultra-violet Rays.*

We have received from the manufacturers (179, Great Portland Street, London, W.1) a sample of material to which they have given the name "Windolite." It has been used by poultry keepers and market gardeners as a substitute for glass, but it is now suggested that, as it allows ultra-violet rays to pass much more freely than ordinary glass, it may be of use in medicine. It is made of acetone cellulose reinforced with wire netting of a mesh about one-eighth of an inch in diameter. It is light and portable, and may therefore be of use in the tropics to form the windows of a country dwelling. It has been examined for us, and it is found that, as claimed, it lets the ultra-violet rays through freely. In the original make it passed the ultra-violet rays through to 275 mm., but in a recent sample down to 232 mm. Ordinary window glass stops the ultra-violet rays shorter than about 320 mm. The active biological rays, so far as the skin is concerned, are those from about 310 to 250 mm., but those between 300 and 290 mm. are particularly active. "Windolite" would probably be useful for open-air shelters and verandahs. A new glass, manufactured by Lamplough (47, Banbury Road, King's Norton), called "Vitaglass," is a "cathedral glass" when rolled, but can be blown as a clear transparent glass. It lets ultra-violet rays through down to 275 mm. It may be useful for skylights, verandahs, and the upper part of windows of hospitals, schools, and nurseries. It may also be found of value for incandescent tungsten filament lamp bulbs.

#### *Metallic Bismuth for Intramuscular Injection.*

Bismuth has been proved to be a spirillicide of specific character. In the treatment of syphilis, intramuscular injections of preparations from various compounds of bismuth have been used with results so encouraging as to stimulate the search for preparations of the metal that will yield still more advantageous effects. One,

which has hitherto given the greatest satisfaction, is a simple suspension of the metal in an isotonic solution of glucose. Such a preparation was described in our issue of March 14th (p. 516). We have now had the opportunity of examining another preparation of this kind. It is made by Messrs. Burroughs Wellcome and Co., and is supplied under the trade name of hypoloid bismuth metal. The metal has a high degree of purity; freedom from impurity is especially important as regards lead, which would be likely to introduce disturbing effects. We note also that the particles are of fairly uniform size, a quality which enables the dosage to be better regulated. The ordinary dose for an adult is 1 c.cm., containing 0.2 gram of the metal.

### PULMONARY TUBERCULOSIS TREATED BY M. SPAHLINGER'S SERUM.

WE have received the following letters with regard to the action of the antituberculous serum made by M. Spahlinger (Carouge, Geneva), recorded in our issue of January 3rd (p. 43), and to subsequent correspondence. They have reference, as will be seen, in particular to the case of "R. G."

SIR,—I should like to deal with two points recently raised in the BRITISH MEDICAL JOURNAL in connexion with my work, a recent illness having prevented me from dealing with them sooner. The first, concerning the clearing of shadows in the radiogram, raised in your issue of January 10th (p. 92), was answered by your review of Dr. Jaquerod's book in that issue (p. 76). This clearing of the shadows is due to "the process of resolution."

The second point concerns the ease of Mr. R. G. I understand that Dr. Trechsel himself is dealing with the letter published on February 21st (p. 387) in a note which he is sending you. When Mr. R. G. started to resume normal life he was seen by Dr. Hudson and Dr. Stephani. The former sent me his report of the case on October 14th and the latter on October 12th, requesting me to forward them to you. Excess of work prevented me from doing this until October 27th. I had nothing to do with the conception of these letters, nor did I see the proofs, and I am therefore unable to understand why your correspondent should mention my name in connexion with them. Dr. Hudson and Dr. Stephani were so impressed with the rapid results achieved by my new partial serum that they considered it their duty to place the facts before the medical profession. May I point out that Mr. R. G. was under Dr. Trechsel's care, and that I had nothing to do with his treatment during his last illness.—I am, etc.,

H. SPAHLINGER.

SIR,—My attention has been drawn to a letter which appeared in your issue of February 21st (p. 387), raising the question whether or not Mr. R. G. had died of pneumonia. As I was the physician in charge, responsible for the diagnosis and treatment, I feel called upon to send you the following details.

Mr. R. G.'s ease was considered as hopeless by Dr. Hudson, Dr. Stephani, and myself. The patient had massive bilateral disease, with cavities, and was in a dying condition. Large quantities of Spahlinger's partial serum were given, and ten weeks later all signs of activity had disappeared; chest signs dried up, temperature and pulse became normal, practically no cough, only a trace of sputum in the morning. The radiogram showed that most of the shadows had disappeared, thus indicating that the process of resolution had been extremely rapid. Thereafter the patient resumed his normal life.

On October 22nd Mr. R. G. stayed out at night insufficiently clad and complained of a chill. The next day he was kept in bed with the symptoms of a severe cold, with high temperature (it was normal on the previous evening) and violent coughing attacks. On October 25th a pulmonary aneurysm ruptured. Mr. R. G. recovered from the haemorrhage, which was profuse, and was not followed by another attack. He developed acute lobar pneumonia and died on November 3rd.

The fact that during his last illness pneumococci only were present in the sputum in large numbers, and that I did not consider it necessary to administer any further doses of Spahlinger's serum, proves my faith in the diagnosis of acute pneumonia as the cause of death.

What was claimed in Dr. Hudson's and Dr. Stephani's letters, which appeared in your issue of January 3rd, and what is also claimed by me to-day, is that Mr. R. G. was in a hopeless condition when Spahlinger's serum was started on August 1st, and that, ten weeks later, the intensive serum treatment had arrested the disease. If an aneurysm had formed in a cavity and ultimately ruptured, surely Spahlinger's treatment could not prevent that. It was an accident which in no way diminishes the favourable impression obtained and the remarkable curative effect produced by the serum.—I am, etc.,

Geneva, March 25th.  
DR. E. TRECHSEL.

# British Medical Journal.

SATURDAY, APRIL 4TH, 1925.

## THE LIBERTIES OF THE PROFESSION.

IN THE BRITISH MEDICAL JOURNAL of March 21st (p. 566) we directed the attention of all medical practitioners to certain proceedings under the Insurance Acts reported in the SUPPLEMENT of that week (p. 122) under the heading, "A fatal case of diphtheria." We recur to the subject because it concerns the rights and liberties of the profession. The report in question was that of a Committee of Inquiry, consisting of a barrister-at-law and two medical practitioners, appointed by the Minister of Health in accordance with the Regulations made under the Insurance Acts, to investigate the professional conduct of a London insurance practitioner (designated by us as "Dr. Z") in respect of his treatment of an insured patient. The London Insurance Committee brought a charge of gross negligence against Dr. Z in failing to diagnose diphtheria until a late stage of the disease, and demanded his removal from the medical list for the County of London. The Inquiry Committee, in its report to the Minister, submitted a full and careful account of its findings of fact, and its findings, we may remark, put a very different complexion upon some of the alleged facts of the case and grounds of complaint formulated by the London Insurance Committee. The Inquiry Committee included in its report certain observations. Of these the one to which the Ministry of Health should have attached great importance, as going to the root of the matter, is as follows: "When a charge of gross negligence is made against a doctor it seems just to avoid an attitude of mind which—to use a colloquial phrase—savours of being wise after the event, and not to attach undue weight to the death of the patient with the obvious exception of cases in which the death can be proved to be attributable to such negligence." In the course of its six inferences of fact the Inquiry Committee exonerated Dr. Z from the very serious allegations made against him. The furthest it went in criticism was the following reference to Dr. Z's omission to take a swab from the throat: "... we can only describe the fact as unfortunate that the respondent, in his persistent diagnosis of tonsillitis, did not adopt this further test for the purpose of checking his opinion." The Committee, moreover, found that "no possible suggestion can be made against the respondent for any neglect in attendance," and it noted the great care exercised by him in the case. "In our opinion," the Committee concluded, "the charge of gross negligence wholly fails. The facts indicate the possibility of criticism of the respondent in the matter of his professional skill, but an illness which commences with tonsillitis and is complicated by the subsequent onset of diphtheria and Vincent's angina is probably not of common experience, and adds to the difficulty of making a correct diagnosis. We think that the complainants were not justified in making their representation and thus putting in motion the machinery which involved the inquiry held by us. In pursuance of this view we recommend that the complainants be ordered to pay to the respondent his taxed costs of the inquiry."

The Minister of Health, in pronouncing judgement, agreed that Dr. Z should receive his costs, but, in

complete disregard of the tenor of the Inquiry Committee's report, informed the complainants that Dr. Z ought to be fined £20, and in order to ensure compliance with this opinion the Minister has withheld £20 from the money payable to the Insurance Committee. The letter from the Ministry of Health to the London Insurance Committee sought to justify the infliction of this fine by reference to some advice tendered from an unnamed quarter. "The Minister," it said, "is advised that some of the symptoms from which, according to the report of the Inquiry Committee, this patient suffered, were such as should have suggested the presence of diphtheria. . . ."

The annotation in the JOURNAL of March 21st ended by inviting the Ministry of Health to send us any explanations it might wish to offer of this strange action; but so far the invitation has met with no response. A question has, however, been asked in the House of Commons, as reported in our Parliamentary columns this week (p. 676). Mr. Herbert Williams, member for Reading, asked the Minister of Health on March 26th why penalties of £10 and £20 were imposed on two doctors, who had been accused by the London Insurance Committee of gross negligence in cases of appendicitis and diphtheria respectively, but had been found innocent by a committee appointed by the Minister of Health. Mr. Neville Chamberlain's reply must be regarded as most unsatisfactory. In particular we would draw attention to two passages. Mr. Chamberlain said that the Inquiry Committee's findings of fact indicated that in one case (clearly that of Dr. Z) "the doctor had failed to exercise reasonable care"; and, later, he said that "there was no ground for the statement that the practitioners were found innocent." As Dr. Harry Roberts remarked in his trenchant letter printed in our last issue (p. 631), "If we stand this we shall stand anything."

On the day before the Minister put forward his defence in the House of Commons this matter had been brought formally to the notice of the British Medical Association, as recorded in the proceedings of Council published in the present issue of the SUPPLEMENT. It arose in connexion with the final draft of the Memorandum of Evidence to be submitted by the Association to the Royal Commission on National Health Insurance. Dr. Brackenbury, in studiously temperate terms, submitted an additional paragraph which he had drafted in regard to the judicial or semi-judicial functions of the Ministry of Health. The paragraph makes reference to the inexplicable action of the Ministry in imposing penalties on practitioners, and says it is exceedingly disquieting to find that, though the machinery set up in agreement with the profession is used, and the agreed procedure is followed, "there are cases in which there seems little or no relationship between the decisions of the Ministry and the reports or recommendations of the bodies on which action is supposed to depend." Emphasis is laid on the point that a strict distinction must be drawn between professional conduct in the attention given to a patient, and the nature of the exact professional treatment given to the patient; and the paragraph closes with a declaration that the propriety or otherwise of any particular method or line of treatment ought not to be made the subject of investigation in connexion with the insurance service.

Dr. Brackenbury told the Council that the grievance would be plainly stated to the Royal Commission by the Association's witnesses, who would say that the profession could not tolerate this sort of procedure if it went on without explanation from the Ministry. These assurances, together with Dr. Dain's significant

remark that the Insurance Acts Committee would have some very definite things to say on the subject to the Ministry of Health, will doubtless be read with satisfaction, not by insurance practitioners alone, but by the medical profession at large. Our profession is not quick to express its feelings; but, unless we are misinformed, it is already gravely concerned for the defence of its freedom against this new kind of attack.

### THE EXPECTATION OF LIFE IN GLASGOW.

MR. WILLIAM JONES, secretary to the public health department of the Corporation of Glasgow, has prepared and published two new Glasgow life tables—one based on the census of 1871 and the deaths registered in the three years 1870-72, the other based on the census of 1921 and the deaths in 1920-22. He is to be congratulated on the completion of a very troublesome task, and, as pointed out in a preface by Dr. A. K. Chalmers, it places Glasgow in what is surely a unique statistical position in having life tables covering a hundred years. The first was published in 1829, and was based on data for the six years 1821-27. The figures, of course, are not strictly comparable as between the successive tables, owing in the earlier data to errors as to population and in the later to extensive additions to the area of the city by absorption, mainly of adjoining burghs. But broadly the statistics do give a very striking picture, first, of deterioration of health conditions owing to the extraordinary growth of Glasgow during the industrial revolution in the earlier part of the nineteenth century, and next, of improvement of health conditions in the past half-century. As is customary in such tables, the figures for the two sexes are given separately.

In 1821-27 the expectation of life at birth was in males 34.12 years and in females 36.64 years. By 1870-72 the corresponding figures were reduced to 30.93 and 32.61 respectively. In other words, the outlook as to survivorship was three to four years worse than it had been forty years earlier. But by 1881-90 the loss was more than wiped out, the expectation being for males 35.18 and for females 37.70, which is just about a year better than in 1821-27. In the next forty years the improvement was very notable, the male expectation being no less than 48.41 years and the female 53.19.

These figures all relate to the whole lifetime, from birth onwards. But so great is the mortality in the early years of life compared with the later that the survivors at the age of 10 years have an average prospect of life longer than the average expectation at birth. Starting therefore to make comparisons at 10 years old, and beginning with the life table of 1821-27, the expectation of life amongst males was 42.27 years, or fully eight years greater than at birth, and in females 45.24, or over eight and a half years greater. It is interesting to note that at this age period the fall in expectation as between 1821-27 and 1870-72 was not so great as in infants, being only 2.12 years in males, though in females it was 3.41 years. Coming to the life table of 1881-90, the 10-year-old children had made a great advance—to 57.70 years' expectation in males and 45.44 in females, which latter figure, however, is only 0.20 better than the original 45.24 of 1821-27. Finally, by 1920-22 the expectation of male children who had survived through the first decade had risen to 50.81 years and of females to 53.19, so that, adding the first ten years which they had already lived, their mean age at death would be 60.81 in males and 63.19 in females.

Under the heading, "The increase in life capital," Mr. Jones submits some striking mass figures, following which he writes: "The present population of the city will, therefore, live among them approximately twenty million more years of life than a similar number of persons fifty years ago, fully nine millions being among males and ten and three-quarter millions among females," but he points out that "proportionately the added years are mainly of adult ages." The details emphasize this reservation. The percentage increase at age 0-4 inclusive is only 2.9, while at 35-54 inclusive it is 30.2, and over 75 years the gain is only 5.2 per cent.

In comparing the life tables of 1920-22 relating to Glasgow, Liverpool, and Manchester, the curious result is shown that in males Glasgow has a slight advantage over both towns (much less over Manchester than Liverpool) at the ages of from 12 to 42 years. Beyond the latter age both Lancashire cities, especially Liverpool, have an appreciable advantage. In females the position is different. At all ages from 12 to 82 (with one fractional exception) both Liverpool and Manchester make a better showing than Glasgow, especially from 12 to 27 years, where Glasgow's expectation is less favourable to the extent of from one year to a year and a half.

Dr. Chalmers makes a most interesting suggestion as to future life tables. He is very strongly disposed to think that they should be built up, not on the general population and its deaths, but on populations grouped according to the number of rooms they occupy and the deaths occurring among them, and Mr. Jones gives some relevant figures based on the census population of 1911. The figures show the expectation of different ages from 10 to 65 according to whether the occupied houses had one, two, three, or four and more apartments, the advantage being with the larger houses. Dr. Chalmers points out that "at 20 years of age the expectation of males in one apartment families was 2.28 years less than the average, and 5.18 years less than in families occupying four apartments and upwards. At 65 these differences almost wholly disappear." With wise caution, however, he does not assume that such differences are to be wholly attributed to housing, and he concludes by observing that "the future of public health administration must concern itself with the elucidation of the causes of these differences."

### NEW DRUGS FOR OLD.

THE use and abuse of drugs was the subject of an animated discussion at a meeting of the Hunterian Society on March 30th, when Mr. H. W. Carson was in the chair. Professor W. E. Dixon, after a reference to the prevailing "therapeutic nihilism" which condemned drugs of all kinds as valueless, said that, while students in this country were taught diagnosis as they were taught it in no other, the teaching of therapeutics was inadequate. A French professor who had been in London for three months said to him that the great difference between French and British medicine was that "we know what to do when we do not know what is the matter with the patients; you know what is the matter with them, and do not know what to do!" Patients were less interested in diagnosis than in treatment, and the physician who had not been properly taught the art of healing was apt to resort to the circulars he received from wholesale druggists with regard to the value of substances the nature and composition of which was sometimes not even stated. In passing, Professor Dixon said a word about vitamins; after stating that fat-soluble vitamin was fixed

in association with the cholesterol of the fats, and was increased as the result of the action of ultra-violet rays, he imagined a future in which mercury-vapour lamps would be suspended over the dining table, throwing down rays to vitalize the food before it was taken! In chemotherapy he found the new outlook in medicine, but chemotherapy must advance further to the production of substances which would be specific in their action against micro-organisms and would not, as did most of the substances now used, kill the body tissues at the same time. Dr. H. H. Dale said that although his time was spent in the laboratory he was not so closely bound up with the scientific method as to demand that the choice of drugs must be limited to those concerning which the fullest scientific knowledge was available. The use of drugs on a supposedly scientific basis was not without danger, which was in many ways greater than that attaching to the use of drugs on the basis of careful clinical experience, for it was very easy, by false and superficial analogies, and by the facile acceptance of any kind of specious explanation, to admit all kinds of things as playing a part in real scientific treatment, whereas in truth what was being done was more irrational than a procedure based upon an enlightened and not too conservative empiricism. At the same time, vague impressions as to efficacy could not be taken as a safe basis for the reasonable use of drugs. Quinine was known to be a specific against the malarial parasite, but what was to be said for the wide use of quinine by the public, largely at the instigation of the medical profession, as a prophylactic against all kinds of catarrhal infections, especially epidemic influenza? There was never a threatened epidemic of influenza but some journal published an interview with "an eminent Harley Street specialist," who advised taking quinine in the form of ammoniated tincture. What real ground was there for the suggestion that it had any prophylactic effect? If there was no real ground the attempt so to use it was an abuse. Again, potassium iodide was known to have a definite specific action on certain forms of chronic infection, particularly tertiary syphilis, but it had come to figure in the list of therapeutic agents as having a general value for reducing swellings and promoting the absorption of effusions of almost every kind. Was there any real basis for that belief? If not, it must be ranked as an abuse of a valuable drug. The salicylates had a specific action in acute rheumatism, but was it not an abuse to prescribe salicylates haphazard for any kind of painful condition of unknown etiology? Medical men were exposed at the present day to some danger on account of their genuine modesty. The people who introduced new drugs had learnt to get at the medical profession on the side of its modesty, for a medical man was prone to receive with quite undue respect any kind of plausible jargon which on the face of it appeared scientific. He quoted some words written by an eminent leader of the profession, now dead, in an introduction to a book which was supposed to give a scientific account of colloids and their use in medicine. This leader, for whom he had the greatest respect, wrote: "It is an obvious desideratum that the drugs employed to combat disease should be in the colloidal state." If he had put it in exactly the opposite way—if he had said that since bodily structures and fluids are colloidal it is an obvious desideratum that any drug should be in the crystalloid state—it would have been just as true and convincing, perhaps even more so. While ready to admit that the colloidal state for certain kinds of medication might have great advantages, and that at the back of it all there was something very valuable from the therapeutic point of view, it was often, Dr. Dale concluded, supported by such a parade of terms from physiochemistry and biochemistry, on the lips of people both inside and outside the medical profession, that it was really time that something was done to resene from abuse what might be a very valuable idea in

treatment. The ensuing discussion was carried on with great animation, and the clocks of Cheapside were approaching midnight by the time the two openers had replied to some little thrusts at the scientific as opposed to the clinical method.

#### THE NATURE OF INHIBITION.

It is a well recognized physiological fact that certain nerve impulses cause a diminution or cessation of activity in the structures upon which they act, but the actual mechanism of this process of inhibition is obscure. In the current number of *Brain* Dr. E. D. Adrian, F.R.S., discusses the various theories which have been advanced as the result of work on the subject in recent years. There are two forms of inhibition, peripheral and central, but it is possible that the differences between them are more apparent than real. Peripheral inhibition is exemplified by the action of the vagus on the heart and by the action of the sympathetic on plain muscle—for example, of the intestine. Now this action of the sympathetic is dependent, as is all sympathetic action, on the liberation of adrenaline at the site of action, probably at the myoneural junction. It is suggested that the inhibitory action of the vagus upon the heart is due to the formation at a synapse or myoneural junction of an inhibiting substance analogous to the adrenaline which is produced by sympathetic activity. That this conception is not entirely theoretical is shown by the experiments of Loewi, who found that the fluid coming from a heart which had been inhibited by vagal stimulation had the property of inhibiting another heart into which it was introduced. Similarly, sympathetic stimulation is said to yield a fluid capable of producing a sympathetic (that is, accelerating) effect on another heart, and it is argued that in the one case an "inhibiting substance," and in the other a "sympathetic substance," must have passed into the fluid. Should these experiments be confirmed, further research will be required into the chemical nature of the "substances" and their mode of action on the muscle fibre. With regard to this last point Adrian refers to a recent confirmation by Samojloff of the experiments by Gaskell on the heart of the tortoise. It is known that during the passage of a contraction through the auricular muscle the active part of the muscle is electro-negative to the neighbouring inactive part, and Gaskell showed that if the auricle was inhibited by stimulation of the vagus the opposite electrical condition prevailed, the inhibited part of the auricle being electro-positive to the rest of the muscle. This alteration of the electrical state during inhibition Gaskell related to a chemical change, and it is possible that such a chemical change is a result of the liberation of the "inhibiting substance." Inhibition as a function of the central nervous system was shown by Sherrington to be a fundamental feature of all reflex movements. If the quadriceps muscle is caused to contract reflexly, as in the knee-jerk, such a contraction is accompanied invariably and simultaneously by relaxation of the antagonistic hamstring muscles—that is, the antagonists are reflexly inhibited. Strychnine and tetanus toxin abolish the reflex inhibition of the antagonists, and both prime movers and antagonists are thrown into powerful contraction in the reflex spasms seen under the influence of these poisons. Sherrington proved that the seat of the inhibitory process in reflex movements is within the spinal cord, and it is conceivable that the inhibition is due to the release at certain synapses in the reflex arc of a specific inhibiting substance such as has been postulated in the case of peripheral inhibition. There is, however, another possibility. If conduction in the central nervous system is governed by the same laws as conduction in peripheral nerves, then, following the passage of any impulse, there must occur a "refractory state" in the conducting path during which the path is incapable of conduction, and is in a state of rest or recuperation. It is

suggested that through the existence of synaptic connexions between the pathways to the prime movers and the antagonists, the impulse which causes contraction in the prime movers may set up a refractory state in the path to the antagonists. All stimuli being thus prevented from reaching the antagonists, these muscles relax at the same time as the prime movers contract. This theory, which has some experimental support, would therefore explain reciprocal inhibition in reflex actions on the physical basis of a refractory state instead of assuming the production of an entirely hypothetical chemical "inhibiting substance."

#### THE GOLD TREATMENT OF TUBERCULOSIS.

Our readers will, we feel sure, be grateful to Professor Moellgaard of Copenhagen for the trouble he has taken to prepare the account of the treatment of tuberculosis by the gold-salt he introduced some time ago, and to which he gave the name "sanoerysin." The use of heavy metals (gold, mercury, copper, and bismuth) for attacking the tubercle bacillus in the body has engaged the attention of many workers during the last twenty or thirty years, but the results have been inconclusive. Professor Moellgaard advances evidence that the gold salt he uses gives encouraging results in certain stages of tuberculosis. It will be seen that towards the end of his paper (p. 647) he says that the curative results obtained in the animal experiments have been secured mostly in cases of the exudative pneumococic type of tuberculosis of the lungs. This type was chosen in order to avoid the variations well known to occur in the chronic type. Other experiments have demonstrated that it is possible to cause typical "productive" tuberculosis to heal in its earliest stages, with sclerosis and calcification, and clinical experience has shown that cases of acute extensive miliary tuberculosis of the lungs can be brought into a condition favourable for healing. The term "productive" tuberculosis puzzled us, and we therefore applied to Professor Moellgaard for an explanation, which he has been good enough to supply. The distinction between exudative and productive tuberculosis of the lungs has reference, he says, to Aschoff's views of the pathological anatomy of pulmonary tuberculosis; these views have been generally adopted in Scandinavia in so far as regards the distinction between exudative and productive phthisis, because the distinction is confirmed by x-ray examination. He applies the term "exudative tuberculosis" to caseous pneumonia in all its stages, not only as a large lobular infection, but as a pneumonic process around other tuberculous foci. These conditions are termed "exudative" because their principal features are exudation of fibrin and white blood corpuscles accompanied by desquamation of the alveolar epithelium, as in the case of other forms of pneumonia. In the x-ray picture they appear as soft formless infiltration like wool, and there is no plenirisy. By "productive" tuberculosis is understood a process the principal feature of which is the building up of new (fibrous) tissue and the production of real tubercles. The x-ray picture shows a spotted and striped infiltration with sharper outlines than in the exudative type. Professor Moellgaard regards the distinction between these two forms as very important in treatment by sanoerysin, because the results of the treatment as shown by the x rays are different. In the exudative cases the infiltrations in the picture disappear almost completely, but in the productive cases the infiltrations grow sharper under the sanoerysin treatment because of the fibrous tissue that is formed. Whether the expectations built upon sanoerysin are fulfilled or not, the line of bases the selection of gold, and of this particular salt of it, will be found both interesting and instructive. The drug is not yet available for general use, but limited supplies have been received by the Medical Research Council, and have

been tested in certain clinical units. The report on the therapeutic results will, we understand, be made available before long.

#### ILLNESS AND DEATH OF JOHN HUNTER.

AN abstract of Sir D'Arcy Power's Hunterian Oration on "John Hunter as a man" was published in our columns on February 21st (p. 379). We then gave some idea of the gist of his address, but time and space forbade such a leisurely consideration of it as its merits deserved. We have now had an opportunity of studying its full text in a well printed pamphlet, and of appreciating the quaint illustrations, reproduced from Jesso Foot's *Life*, by which it is adorned. The author of the last mentioned scurrilous work had a considerable practice among sufferers from venereal disease, but no valid claim to be considered as a rival of Hunter, whom he consistently abused, while he denied to him all originality and attributed the authorship of his works to Tobias Smollett. The Orator justified his choice of a subtitle—"A martyr to science"—by bringing forward evidence that John Hunter's long and severe sufferings were due to the syphilitic infection which followed his self-inoculation. This was, indeed, an outstanding feature of the Oration. No new literary material was available, but Sir D'Arcy Power reviewed in turn the record of each illness from which Hunter suffered, and stated his opinion that the symptoms were indications of syphilitic disease of the arteries at the base of the brain. This view may be right; it is impossible to declare it erroneous, so that it may be held out of place to question it. Yet if Sir D'Arcy Power's view becomes established, the writings of Hunter may come to be regarded as the products of a sick brain. But is such a conclusion necessary? Cases involving the same question are common—that is to say, infection by syphilis, the manifestations arrested in the early secondary stage by mercurial treatment, and in later life symptoms indicating arterio-sclerosis. It is to be remembered that Hunter's brother William had died at the same age, 65, after presenting similar symptoms. Hunter inoculated himself in 1767. He died on October 16th, 1793. His own account of the results of his inoculation includes an expression of his opinion thereon—"The time the experiments took up, from the first insertion to the complete cure, was about three years" (Works (Palmer), 1835, ii, 419, para. 3). His body, including the brain, was examined *post mortem* without any lesion being noted which would now be certainly attributed to syphilis. The viscera of the belly and head were found loaded with blood, but otherwise nearly in a natural state, with the exception of the carotid arteries and their branches within the skull, which were in parts thickened and ossified. In the chest the left lung had become attached to the costal pleura by old and firm adhesions; but the heart was found to be the chief seat of disease. The pericardium was unusually thickened, but did not contain much fluid. The heart itself was small, appearing too little for the cavity in which it was contained; its diminished size was the result of wasting, and not of strong contraction of its fibres. Two opaque white spots were seen on the left auricle and ventricle respectively. The muscular structure of the organ was pale and loose in texture. The branches of the coronary arteries which ramify through the heart were converted into long tubes, with difficulty divisible by the knife. The mitral valves were much ossified. The aorta was somewhat dilated, its valves thickened and wanting pliancy, and the inner surface of the artery was studded with opaque and elevated white spots (Works (Palmer), 1835, i, 132). It may fairly be asked what firm grounds there are for going beyond the statement that Hunter suffered from angina pectoris due to arterio-sclerosis. Both Sir William Osler and Sir James Mackenzie referred to Hunter as a type of

arterio-sclerosis without adding anything as to syphilis, Mackenzie going on to remark that the brain was not involved. Sir D'Arcy Power has gracefully dedicated the reprint of his own oration to a former Hunterian Orator (1869), his own well beloved father, Henry Power, ophthalmic surgeon to St. Bartholomew's Hospital, whose ability, as well as his personal charm, is manifest again in this worthy successor.

#### THE STRUCTURE OF THE ATOM.

IN the Friday evening discourse at the Royal Institution last week Sir Ernest Rutherford unfolded the fascinating story of the inquiry into the structure of the atom, and the nature of the forces which surround its nucleus, which has been proceeding at the Cavendish Laboratory, Cambridge. During the past year he and his co-workers continued to bombard the atoms of various elements with the alpha particles of radium or radio-active substances. The alpha particle is the most energetic projectile known; it has a velocity of 10,000 miles a second, and it is capable of ploughing its way through the structure of any atoms in its path. The atoms of the different elements all have a minute charged nucleus, surrounded at a distance by a number of electrons in motion. Sir Ernest Rutherford represented the nucleus by a small handball on the lecture table, and said that the nearest electron on this analogy would be about as far away as the distant wall of the theatre. By the law of probability, therefore, the collisions of alpha particles with the charged nucleus cannot be frequent, and it has been necessary to make very numerous observations of the effect of bombardment in order to discover what happens when the alpha particle gets into the intense electric field of the nucleus. From a study of the angle of deflection of the particle in such circumstances it has been hoped to find out what it is that holds the atom in equilibrium, the laws of force which operate between the alpha particle and the charged nucleus, and the nature of nuclear structure. On the basis of experiments on aluminium and uranium, Sir Ernest Rutherford put forward the hypothesis that each nucleus of an atom is surrounded at a little distance by a circle of electrically charged doublet-satellites—a sort of Saturn's ring—continually rotating. It was, however, easy to get on an entirely wrong track, and to make illusory discoveries, a good deal harder to disprove than to make. Patient investigation has been undertaken by Mr. Blackett, under Sir Ernest Rutherford's direction, and a long series of photographs of bombardments have been produced by an automatic camera device, whereby the tracks of half a million alpha particles have been studied. Now and then a disintegrating collision has been observed, and the story of it has been read in the scattering and deviation of the straight luminous lines on the photographic plate. So far it has not been possible to say what happens to the alpha particle after its collision with the nucleus. Sir Ernest Rutherford suggests, on the basis of eight photographs which have been obtained of a disintegrating collision between the alpha particle and the atoms of nitrogen, that the alpha particle may be captured by the nucleus as a result of what would be called in military strategy an encircling movement. A proton is ejected, and its fainter track can be discerned; but unless, in Sir Ernest Rutherford's words, an unseen electron has "dodged off," the alpha particle which is driven into the recoiling nucleus is imprisoned within its system. The result of bombardment by alpha particles, therefore, may be a synthesis, a building up or replacement, rather than a disintegration, in the case of a light nucleus. But years have been spent upon this study, and more years will have to be spent before the riddle of atomic architecture is solved. The term "proton"—meaning rudiment—has been borrowed by the physicists from the biologists.

#### MEMORIAL TO SIR WILLIAM MACEWEN.

WE published last week (p. 615) the first list of subscribers to the fund to establish a memorial in Glasgow to Sir William Macewen. The amount announced in the list was £1,550, or about half that desired to carry out the three objects of the memorial—namely, a bust for the University with a replica for Lady Macewen, a Macewen memorial lectureship, and a Macewen medal or prize in surgery for students. We feel sure that many members of the British Medical Association, remembering Sir William Macewen's great services to it, will be anxious to subscribe. They may send their gifts to the Financial Secretary of the British Medical Association (Mr. L. Ferris-Scott), 429, Strand, London, W.C.2, who will forward them to the treasurer of the fund, Mr. James Macfarlane, D.L., LL.D., Wesleyan Street, Glasgow, S.E. Cheques and postal orders should be made payable to the Sir William Macewen Memorial Fund.

#### BRITISH CONGRESS OF OBSTETRICS AND GYNAECOLOGY.

WE announced three weeks ago that the fifth British Congress of Obstetrics and Gynaecology would be held in London on Wednesday, Thursday, and Friday, April 22nd, 23rd, and 24th, under the presidency of Dr. H. Russell Andrews. It has been promoted by the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, London, the Edinburgh Obstetrical Society, the North of England Obstetrical and Gynaecological Society, the Midland Obstetrical and Gynaecological Society, the Section of Obstetrics and Gynaecology of the Royal Academy of Medicine, Dublin, and the Ulster Medical Society. The chairman of the executive committee is Dr. T. W. Eden, and the treasurer is Mr. T. G. Stevens; the other members are Professor W. Blair Bell (Liverpool), Dr. R. W. Johnstone (Edinburgh), and Professor Sir Ewen J. Maclean (Cardiff). The official guests are Professor J. Whitridge Williams (Baltimore) and Professor W. W. Chipman (Montreal). The meetings will be held at the house of the Royal Society of Medicine. The meetings in the morning and afternoon of the first day will be devoted to a discussion on the prognosis and treatment of puerperal sepsis. Two reports on the subject have been drawn up—one by a committee of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, and the other by a committee of the North of England Obstetrical and Gynaecological Society. Copies of these reports can be obtained from Mr. Clifford White, one of the honorary secretaries of the Congress, if application is made to him before April 10th. At the morning session communications will be made by Sir Ewen J. Maclean on puerperal sepsis in Wales and by Dr. Gibbon Fitzgibbon and Dr. J. W. Bigger on a clinical and bacteriological investigation of puerperal fever, and Dr. L. P. Lockhart will relate the results of bacteriological examinations during pregnancy. A discussion on puerperal sepsis will be opened in the afternoon by Professor J. Whitridge Williams. At the morning and afternoon sessions on Thursday and at the morning session on Friday individual papers will be read: on the afternoon of Friday operations will be performed at most of the principal hospitals. A pathological exhibition will be open during the whole of Thursday and Friday, and members who wish to exhibit specimens are requested to communicate at once with the secretary of the pathological committee of the Congress, Dr. Everard Williams, 5, Wimpole Street, W.1. There will be a luncheon on Wednesday, and in the evening the President and Mrs. Russell Andrews will hold an "at home" at the Royal Society of Medicine. The Congress dinner will take place on the evening of Thursday. Further particulars can be obtained from the honorary secretaries, Mr. Clifford White, F.R.C.S., 62, Harley Street, W.1, and Mr. J. Barris, F.R.C.S., 50, Welbeck Street, W.1.

# THE THERAPEUTICS OF RADIUM.

## THE EXPERIENCE OF THE RADIUM INSTITUTE, LONDON.

THE first hint of the radio-active properties of certain elements was obtained by M. Henri Becquerel of Paris. Professor Röntgen had made his memorable discovery of the  $x$  rays in the previous year (1895). Becquerel was interested in phosphorescence, and asked himself whether phosphorescent light was entirely stopped by opaque objects, or whether in part it consisted of invisible penetrating rays, like the  $x$  rays. By great good fortune the phosphorescent body he chose was uranium. He wrapped a photographic plate in black paper and placed the phosphorescent substance on it and then exposed it to sunlight. The photographic plate beneath the substance was dark, showing that it was giving out rays that, unlike sunlight, were capable of penetrating the black paper. Becquerel then discovered that the darkening of the plate wrapped in the black paper occurred as much in the darkness as in the light. It was then ascertained that three different types of rays were given out by the radio-active substance; they were called the alpha, beta, and gamma rays. The next step was the discovery (1898) by Madame Curie and her husband and G. Bémont of radium, an element over a million times as radio-active as uranium. The  $x$  rays had already been applied in diagnosis and therapeutics, and it was not long before radium also was used for these purposes.

The Radium Institute in London was founded on the initiative of King Edward VII, and with munificent gifts from Sir Ernest Cassel and the Earl of Iveagh. The building specially erected for the purpose in Riding House Street, Portland Place, was opened in August, 1911, and has since been enlarged more than once, the last addition having been taken into use at the beginning of this year. The Institute has been conducted on the lines of a charitable trust, no appeal being made for public support, but patients are expected to contribute within their means. For those able to pay for treatment in the Institute several private bedrooms were provided two years ago, and early this year two new wards for the treatment of necessitous patients were added. They provide four cubicles for women and three for men, and form part of a self-contained unit with a small operating theatre for the performance of minor operations—the "surgery of access."

The first report of the Institute, dealing with the period from August 14th, 1911, to December 31st, 1912, was published in its entirety in this JOURNAL (January 25th, 1913, p. 149). The report for the next year was published by the Institute itself as a pamphlet, and this has been the practice since. The reports have been fully analysed year by year in our columns, and the information they contained has been of great value to the medical profession, owing to the large number of cases treated and also to the candour and impartiality with which the results have been recorded by the medical superintendent (Mr. A. E. Hayward Pinch, F.R.C.S.). The previous annual reports have dealt with the work of the preceding year, have described the apparatus used and improvements made in it, have discussed the best methods of application, and have set out the lessons learnt under the heads of the various diseases treated.

### "A CLINICAL INDEX OF RADIUM THERAPY."

This year a new departure has been taken, and Mr. Hayward Pinch and his assistants, Dr. Philip Gosse and Dr. Oskar Teichman, together with Dr. R. Douglas Reid (house-surgeon), have compiled what they have called *A Clinical Index of Radium Therapy*.<sup>1</sup> Dr. J. C. Mottram,

<sup>1</sup> The Committee of the Institute has authorized the free distribution of the book to members of the medical profession. Copies can be obtained post free on application to the Secretary, Mr. Thomas A. Garner, F.R.C.S., Radium Institute, 16, Riding House Street, London, W.1.

director of the pathological laboratory, has contributed a chapter on the clinical aspects of the work of the research department, and Mr. W. J. S. Alton, F.I.C., director of the chemico-physical laboratory, another on the evolution of the present-day technique of the preparation of radium and radon apparatus. The first seven chapters are concerned with the physics of radium, its disintegration products and the rays emitted, with the use of applicators, with the local and general reaction, with the effect of radium rays on normal tissues, and with the fundamental principles of radium therapy; then follow ten chapters in which the application of the rays to diseased conditions is fully discussed, region by region. The volume is therefore of the nature of a textbook, and in what follows we will ask the reader to bear this in mind, for an attempt to review a textbook in detail is rather a thankless job. We shall pick out only a few points.

### Radon.

In the first chapter, and in Mr. Alton's appendix, the methods of collecting, purifying, and bottling radium emanation, now called "radon," are stated in full. They have been greatly improved during the last few years, and two methods are fully described and illustrated—the one by chemical and physical separation, and the other a purely chemical method. The former is preferred at the Institute. In it the radon is collected in capillary glass tubes, which can be made of any convenient size and form. The smallest in use is 0.3 cm. long and 0.1 cm. wide, and is usually charged with between 1 and 2 millicuries of radon. Others are made up to 5 and even more centimetres long. These tubes are termed "seeds," and are buried in growths without any metal screening and allowed to remain there permanently. "Seeds" is perhaps not a very happy term, because, far from containing any promise for the future, the radon is rapidly disintegrating. This rapid loss of radio-activity is an objection to the use of radon, but the rate of loss is known; it falls to one-half in 3.85 days and to one-fifth in 8.5 days; during the first twenty-four hours radon loses exactly 16 per cent. of its activity. It is therefore a simple matter to prepare a radon apparatus the mean activity of which for twenty-four hours shall be equal to that of a radium salt apparatus of known strength.

In the same way, for the sake of example, it is desired to give an idea of the duration of a radon tube, the value equal to that emitted by 100 milligrammes of radium element. A radon tube is made with an initial radio-activity of 109-110 millicuries; by the end of twenty-four hours its value will have decayed to 92.93 millicuries, so that its mean activity for the whole period will be as nearly as possible equivalent to that of 100 milligrammes radium element."

According to Mr. Alton the use of radium for the production of radon applicators is becoming general abroad, especially in the United States, and we observe that the Middlesex Hospital has recently adopted it. Whether a radium or radon applicator is used is a matter of convenience, the therapeutic effect is identical, as was to be expected, since both depend for their efficacy on the same disintegration products. Modern institutions should be equipped with facilities for the employment of both types. According to Mr. Pinch and his colleagues the advantage of the general use of radon is that its intrinsic worth is small, so that if an apparatus is mislaid or stolen there is no pecuniary loss beyond the value of the container and screens. On the other hand, the radio-activity of a radium salt applicator is always constant for any length of time, and an apparatus if carefully handled needs little attention beyond repairs to its covering at long intervals. The radon applicator must be replaced every few days.

### "Surgery of Access."

In an article published in this JOURNAL on January 17th last (p. 133) it was said that what is called "surgery of access" had been greatly developed; it is now, we are

told, the general rule in radium therapy that whenever the burying of a tube or tubes in a growth is possible this method of treatment should be adapted. If embedded in the centre of a mass the whole activity of the tube is effective, whereas if merely laid upon the surface of a growth little more than 30 per cent. of its rays come into action. Minor surgical operations are therefore performed to permit embedding, especially in the treatment of malignant disease of the breast, uterus, bladder, prostate, tongue, fauces, larynx, oesophagus, and stomach. The method is not suitable for growths of the parotid, carcinoma of the thyroid, and lympho-sarcoma of the neck, as all these show a tendency to fungate rapidly when any breach of the covering skin has occurred. In the other conditions enumerated the use of one or two large tubes containing from 25 to 100 mg. of radium element is being superseded by the use of many smaller tubes containing from 1 to 5 mg. In this way a more equal and effective radiation of the mass is obtained. The small size of the tubes enables them to be inserted rapidly and with the minimum of disturbance of the tissues and discomfort to the patient. The importance of getting the surface as surgically clean as possible before burying the tube is mentioned; thus in lesions of the mouth and fauces carious teeth should be extracted or stopped, and in carcinoma of the cervix it may be found advisable to keep the patient in the ward for some days to permit of thorough cleansing of the vagina and cervix, curettage of exuberant masses, and subsequent douching. In carcinoma of the bladder, if there is no cystotomy opening, tubes may best be inserted by means of a special operating cystoscope. In malignant disease of the oesophagus the introduction should always be performed under direct oesophagoscopy. When screen tubes of radium are buried in dense tissues a passage must be made with a tenotome or trocar, and for the introduction of the very small capsules of emanation a trocar and cannula can be used.

#### Reaction.

The chapter on reaction, though short, is highly important. The application of radium (or radon) is always attended by some reaction of the tissues, but its degree and extent varies, and the factors causing these variations are not well understood. There is such a thing as personal idiosyncrasy. In patients of a highly neurotic temperament the local systemic reactions are much more likely to be pronounced than in those of a phlegmatic type. Persons who freckle easily often develop pigmentation of the area treated after a lapse of several months. Age also makes a difference; the surface reaction develops earlier and is more intense in infants than in adults, and when treating infants for extensive capillary naevi it is advisable to proceed with great care until the degree of susceptibility has been clearly ascertained. Again, the reaction in patients suffering from locomotor ataxy, syringomyelia, paralysis, or any disease or operation affecting the functions of the trophic nerves is often excessive. For example, the elaborate and extensive dissection associated with the performance of Wertheim's hysterectomy appears to impair the vitality of the pelvic tissues, so that special caution must be exhibited in making exposures within two or three months after operation. Tissues which have previously received much treatment by x rays or ionization or have been cauterized or subjected to the action of carbon dioxide snow should be treated with much care, as any over-dosage may result in excessive breaking down of the old scar tissue. General reactions also occur when a large quantity of heavily screened radium has been employed and prolonged exposures given. Such systemic reactions are best seen in the treatment of lymphadenoma, lympho-sarcoma, and sarcomatous growths generally. The symptoms are those of toxæmia. The key-note of all this chapter is the need for caution.

Speaking generally, the degree of reaction depends upon the apparatus, screening, and dosage employed, on the extent of the area treated, and on the nature of the tissue. Mucous surfaces are much more susceptible than the skin—the reaction appears earlier and lasts for a longer time. The skin reaction is less in a dry surface than in a moist; vesication occurs more readily in such situations as the axilla and inguinal folds than at other parts. Finally,

carcinomatous or sarcomatous tissue does not display the same resistance to radium rays as normal cells, and it is upon the proper and correct appreciation of this fact that successful radium therapy in such cases largely depends. In a typical skin reaction, following upon treatment with unscreened or lightly screened apparatus emitting a large proportion of beta rays, four degrees may be distinguished: (1) simple erythema; (2) erythema followed by vesication; (3) vesication with superficial ulceration; and (4) deep ulceration generally followed by the formation of "limpet shell" radium crust beneath which repair takes place. The reaction in the skin usually begins to appear between the seventh and fifteenth days, and may never go beyond slight erythema. In other cases the interval may be longer—as much as three weeks. When radium or radon tubes are buried in the tissues the reaction depends largely upon the character of the screening; it is greater with thick screens, owing to the secondary radiations produced. Special means, therefore, must be taken for their absorption.

#### Fundamental Principles of Radium Therapy.

Given sufficient intensity and length of exposure the effect of radium emanations upon a living cell is, first, increase, then the arrest of cell activity, and finally a degeneration of the cell. These stages pass more quickly in a pathological condition than in a healthy cell. In radium therapy, therefore, the aim is to give such a dose and length of time as will cause the death of the pathological cell without appreciably affecting the functions and vitality of the normal cells. In this connexion the general condition of the patient is of importance, and cachexia militates against successful treatment. "Speaking in very general terms," we are told, "it is best to give a maximum dose at the first exposure."

#### The Treatment of Disease.

The remainder of the book, as has been said, deals with the treatment of disease, malignant and other, in various regions. There is a chapter on radium and internal medicine, which shows that this department of the subject is still in a rather empirical stage. The book will without doubt be, as its authors hope, of great use to general practitioners in enabling them to recognize the possibilities and limitations of radium therapy. No extravagant claims are made. The repute of radium therapy, it is truly said, has suffered from the irrational enthusiasm and unthinking expectations which so often attend the appearance of a new remedy, but it cannot be denied that radium as a therapeutic agent has great power. The preface concludes with the following modest statement: "With increased knowledge and improved technique it may be hoped that the time will come when the word 'cure' may be used deliberately and justifiably with regard to the radium treatment of a constantly increasing number of cases of malignant disease."

#### RADIUM IN DUBLIN.

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, held on February 27th, Mr. SETON PRINGLE in the chair, Mr. WALTER C. STEVENSON gave a summary of radium treatment in Dublin during the year 1924.

Mr. Stevenson had treated altogether 174 patients, 105 of whom were suffering from malignant and 69 from non-malignant conditions. He employed mostly radium emanation in glass capillary tubes, supplied by the Irish Radium Committee, supplementing this with 53.53 mg. radium element in six capillary metal tubes. Since, in the majority of cases of malignant disease, treatment was symptomatic only, many cures could not be expected, yet many gratifying results had been obtained. Excluding 5 rodent ulcers cured, an apparent cure or the complete arrest of the disease was obtained in 15 cancers (1 lip, 3 tongues, 1 antrum, 4 breasts, 1 body of uterus, 5 skin cases) and 4 sarcomas of the neck and 1 of the thigh. He gave full details of the treatment in one case of apparent cure of cancer of the tongue, and indicated the doses employed in several other conditions. He emphasized the better results obtained by using larger quantities of radioactive material and distance pieces, which enabled a larger

dose to be administered and absorbed by the tissues in a more uniform manner. In non-malignant conditions the effect of radiation, continued for a long time, was most marked. In two cases of tuberculous peritonitis there appeared to be a complete recovery. Many scars, painful and otherwise, were treated with good results, and patients with painful stumps following war injuries were enabled to wear their artificial limbs. Among the non-malignant cases treated with satisfactory results were actinomycosis, corns, Dupuytren's contraction, fibroids of the uterus, fissure of the tongue and lip, Hodgkin's disease, keloid, lumbago, neuralgia, osteo-arthritis, pruritus ani, sinuses and ulcers, sciatica, spring catarrh, and warts. Mr. Stevenson also demonstrated his radium apparatus, consisting of brass boxes, needles, and series of six brass tubes of various sizes with interchangeable blunt, olive-pointed, and trocar-pointed ends. By the use of extension pieces, made up of short lengths marked in centimetres, which screwed into one another and into the radium container, a series of tubes or needles could be inserted into a tumour from end to end. Systematic radiation was obtained by introducing the radium at intervals into untreated areas, segments of the extension piece being screwed off as they appeared at the skin level. Tubes and needles were easily inserted trocar-fashion, the skin being first stabbed with the point of a knife. He also showed an aluminium distance piece for vaginal and rectal work, and an apparatus for fixing the wire screwed into a radium tube in the oesophagus; the radium could thus be moved as required without disturbing the patient or the dressings.

Dr. M. R. J. HAYES, reviewing his cases in 1924, stated that the treatment of rodent ulcer by radium gave excellent results. With correct dosage and filtration one application usually sufficed; the scar was scarcely perceptible and recurrences were rare. Rodent ulcers on the eyelids should receive fractional repeated doses rather than a single full application, since severe conjunctival reaction and photophobia followed massive doses in this region. The eye should be carefully protected by adequate filters from unnecessary and harmful radiation. If the ulcer had invaded bone or cartilage radium would not cure it, and the invaded tissue must be excised. Of 27 cases treated in 1924, 23 had healed and 4 were still under treatment. Two early cases of carcinoma of the lip and two recurrent cases healed rapidly after surface applications of radium. The cervical lymphatic glands were simultaneously irradiated, whether enlarged or not. Patients with inoperable and advanced carcinoma of the floor of the mouth were benefited, and although a cure could not always be expected the advance of the disease was retarded, and there was considerable relief from pain and suffering. Seven inoperable cases of carcinoma of the os and cervix uteri had been treated, and all were improved, pain, haemorrhage, and fetid discharge being arrested. Two patients died within a few months from metastases in other organs. One, aged 63, who was first treated in July, 1921, was still alive and healthy, and the disease had been kept in check. Since the maximum effect of radium was local the high-voltage  $\alpha$  rays were better than radium rays in obtaining uniform and homogeneous distribution of irradiation at depths inaccessible or dangerous for the implantation of radium needles. Three cases of fibrosarcoma and one of osteosarcoma showed considerable improvement after treatment. An inoperable case of carcinoma of the rectum in a man, aged 43, who had had colostomy performed in 1923, was treated by radium in December, 1923. Following this his pain, tenesmus, and discharge disappeared; he had put on weight, and was now able to perform his daily work without any discomfort or inconvenience.

Mr. H. H. POOLE referred to the relative efficiency of radium and  $\alpha$  rays with regard to deep  $\alpha$ -ray therapy. From the physical point of view, he supposed that the therapeutic action was purely a question of ionization, the only difference being that gamma rays were harder than any  $\alpha$  rays that could be produced. The beta rays produced by radium were of a much higher velocity, and had a greater penetration than those produced by  $\alpha$  rays; gamma rays were probably better for absorption. The real difference

between the action of  $\alpha$  rays and the action of beta rays was that with  $\alpha$  rays a very large amount of energy was available, and a much more uniform depth was obtainable, though with radium a somewhat similar effect could be obtained by large surface doses spread over a wide area of skin. The ionization produced by beta rays was approximately one hundred times greater than that produced by gamma rays, the reason being that the ionization was all concentrated in such a small depth.

Mr. S. PRINGLE said that the results obtained by radiologists were improving every day, and cases in which it would have been impossible to recommend any treatment at all five years ago were now being treated by  $\alpha$  rays and radium. In some of them the results were quite good, and he thought that better results could be hoped for in the future. It was only in comparatively superficial growths that a good result could be expected, though with the deeper growths the results were encouraging. Very few real cures could be hoped for from radium or even from deep  $\alpha$ -ray therapy, but he believed that with improved technique and greater knowledge it would be possible to deal with conditions that were at present outside the scope of treatment. He always radiated his patients who had suffered from cancer of the breast. Patients had been kept alive by means of  $\alpha$  rays before radium had been used, and their pain had been relieved for many years; in some cases the growth disappeared altogether but recurred some time later. He thought that in the future, when once the primary growth had been removed, the prophylactic post-operative treatment by  $\alpha$  rays and radium would be greatly improved.

Mr. W. C. MacFERRIDGE thought all cases of rodent ulcer of the eyelids should be treated by radium, if the ulcer was at all large. He had treated four cases of rodent ulcer recently; in one the ulcer was very small, and he excised it, which was the right treatment if the ulcer was small and could be excised without producing any deformity. In most cases, however, the ulcer was too large for excision, and radium was the treatment employed. Cases had been reported in which damage had been done to the cornea and the lens, but he, personally, had not seen a case in which this had occurred.

Dr. D. J. CANNON referred to the treatment of skin cases by  $\alpha$  rays and radium; in Vienna the treatment was largely used, with very good results; it had to be continued for a long time. He thought that radium was pre-eminently successful in cases of gynaecological haemorrhage and some cases of fibroid. Haemorrhage which resisted all other forms of medication could be cured by one application of radium or  $\alpha$  rays. This treatment, however, should not be used in patients who were suffering from pressure symptoms as well as from haemorrhage. He had recently had a case of haemorrhage occurring ten years after the menopause, and he suspected carcinoma. There was no evidence of degeneration and no pain, only haemorrhage. After one dose of radium the patient was cured and had no recurrence of the haemorrhage. The etiology of haemorrhage in young women was obscure; hypofunction of the ovary was suspected. These cases were, sometimes cured by small stimulating doses of  $\alpha$  rays.

## England and Wales.

### HEALTH ADMINISTRATION IN LONDON.

At its last two meetings the London County Council has had before it the lengthy report of a special committee on health administration in London, over which the new chairman of the Council, Captain Oscar Warburg, has presided. In view of a recent statement by the Minister of Health that he was giving attention to a new health bill, the time seemed opportune to the committee to consider problems awaiting solution in respect to London health services. A report was made to the Council by a similar committee in 1919, offering suggestions as to the general lines of a scheme for the better organization of such services, but only two important changes in that direction have since been effected. One is that by the combined operation of the National Insurance Act, 1920, and the

Public Health (Tuberculosis) Act, 1921, the legal responsibility for the institutional treatment of tuberculous insured persons has been transferred from Insurance Committees to local authorities, which were already responsible for the institutional treatment of tuberculosis in respect to the remainder of the population. The other is the formation of voluntary hospitals committees, as recommended by Lord Cave's committee, and the acceptance by King Edward's Hospital Fund of the functions of voluntary hospitals committee for the metropolis. Otherwise no special progress has been made towards the co-ordination of health functions during post-war years. No action has yet been taken to remove the anomalies and inconveniences arising owing to the Poor Law medical service being administered separately from the health services under municipal authorities. This is one of the questions awaiting national solution. The view of the committee is that the health functions of London Poor Law authorities should be divided between the County Council and the borough councils, and the Poor Law institutions transferred to the ownership and management of the County Council. It would then be possible for the Council, after conference with the King Edward's Hospital Fund, to advise the Minister of Health as to the total hospital provision to be made by public authorities. Other matters awaiting a national solution included the legislation on the use of preservatives and colouring matters in food, the amendment of Part I (infant life protection) of the Children Act, the tightening up of the Cleansing of Persons Act, regulations for the more effectual perfilation and ventilation of places of public entertainment and the exclusion of children therefrom as a precautionary measure when necessary against the spread of epidemic, endemic, or infectious disease, and the revision and codification of the existing enactments with regard to serious emissions of smoke. Certain local problems which involve other authorities besides the County Council include the disposal of house and other refuse as it affects the development for residential or industrial purposes of certain lands on the eastern outskirts, and the disposal of sewage from London and adjacent areas draining into the Thames. Of the problems affecting particular services the most important is the development of a comprehensive scheme for the treatment of tuberculosis. An early settlement as to the future of Poor Law infirmaries would advance the solution of the problem of making proper provision for advanced cases of tuberculosis, for the infirmaries could be utilized in part for residential accommodation. Inquiry is to be made into various questions of tuberculosis after-care, in particular the establishment of workshops, and the Council is to give evidence before the Royal Commission on National Health Insurance to the effect that insurance funds might suitably be applied towards approved work centres and other assistance for tuberculous persons. General health propaganda work has developed considerably in London during the past few years, and the committee recommends a further extension of the powers of the Council in this respect, also further periodical surveys—such as that now proceeding on the provision of treatment and education of children suffering from encephalitis lethargica—and periodical conferences with other authorities working in the same field. A number of recommendations were appended to the report, calling for action by the Government on the various matters above set out so far as such action was necessary to effect them. After some Labour criticism on the ground that the proposals were not sufficiently comprehensive and definite, the recommendations were carried.

#### THE LIVERPOOL SCHOOL LABORATORY AT SIERRA LEONE.

On the eve of their return to Sierra Leone to resume work as director of the Sir Alfred Jones Tropical Research Laboratory, Professor D. B. Blacklock and Mrs. Blacklock were the guests of Sir Francis and Lady Danson at luncheon at the Exchange Station Hotel, Liverpool, on March 20th. In the absence of Sir Francis Danson, who was detained in London, Dr. Richard Caton, chairman of the Liverpool School of Tropical Medicine, presided. He said that the luncheon was given for the purpose of bidding good-bye to Professor and Mrs. Blacklock, who were returning to Freetown, where they were doing excellent work in

tropical research. Dr. Caton said that the work carried on by the Liverpool school, which owed its foundation to the late Sir Alfred Jones, was of great benefit, not only to Europeans who resided in the tropics, but also to the native population. Every endeavour was being made to make the tropics more healthy, and thus improve the conditions under which trade could be carried on. The Lord Mayor of Liverpool, speaking as a commercial man, said that thanks were due to those who went out at the risk of their lives in the interest of science and for the benefit of future generations. He hoped that the money necessary for the maintenance of the laboratory—about £2,000 a year—would be shortly forthcoming. Professor Blacklock gave an account of some of the work conducted at Sierra Leone. During the last eighteen months the first subject investigated was schistosomiasis, and with Mrs. Blacklock's help he had been able to determine the species of snail which transmitted it. Two expeditions had been made for the investigation of goitre and to study the sanitation of native villages. Great improvements in the villages might be expected if the native could be educated to develop the natural resources of the country. As it was the sanitary conditions were very bad and the infantile mortality high. The best way to educate the native in hygiene was by demonstration, and that was what the school was endeavouring to do.

#### BIRMINGHAM GENERAL HOSPITAL.

On March 29th, 1924 (p. 596), we referred to the urgent need of increased accommodation for the Birmingham General Hospital. During the past year definite advance has been made in this direction. It is proposed to obtain the upper half of an adjoining churchyard for the erection of new buildings, and negotiations have been in progress with the Bishop, the City Council, and other authorities. It has been found necessary to promote a private bill to give authority for the demolition of the church, to close a street, and to remove human remains. The bill in question is still before the House of Lords, and it is hoped that parliamentary sanction will soon be obtained. The approval of the Bishop and the City Council was given, and the Executive Committee of the Hospital Saturday Fund, after a careful examination of the very urgent need of the hospital at the present time, and of its inability to undertake a larger scheme, have now agreed that the present proposals should be adopted in their entirety. The board of governors of the hospital has decided that the provision of more operating theatres—should be taken in hand at once in order to lessen the congestion due to the attempt to treat a large number of urgent surgical cases. It is hoped that actual building may be begun shortly, the cost (£7,000) of this part of the extension being provided from the invested funds of the hospital. The annual report of the hospital shows that during the past year the number of in-patients was 6,868, as compared with 6,153 in the previous year; the number of out-patients had similarly increased, from 47,696 to 51,777. More than 7,000 operations were performed in 1924. The income for the current year was £68,000, the expenditure £73,000. An increase in income has occurred each year for ten years in succession; the present deficit is due to the fact that the amount received from legacies in 1924 was considerably less than in the previous year.

#### MILL ROAD INFIRMARY, LIVERPOOL.

Three new departments, including an operating, an x-ray, and an electro-therapeutic department, were opened on March 24th, at the Mill Road Infirmary, Liverpool. The scheme of the operating department was devised by Dr. R. T. Bailey, medical superintendent, and Mr. O. Herbert Williams, visiting surgeon. This building is on the ground floor in a courtyard between two ward blocks. Around a central octagonal compartment, large enough for the simultaneous reversing in it of two ward ambulances, are two operating theatres and anaesthetic rooms, an instrument sterilization room, a laryngological theatre, and a cystoscopy room. A dressings sterilization room, a store room, a robing room for the surgeon and assistants, with a shower bath and lavatory and a robing room for nurses, are also provided. Each of the operating theatres is

25 feet long by 16 feet broad, and is lit by a north light; the central octagonal space is lit by a dome. The artificial lighting is designed to eliminate all shadows, and special attention has been paid to avoiding all sharp corners throughout the new buildings so that rigid surgical cleanliness may be obtained. The new building will be of great value to the infirmary, which contains 900 beds, and dealt with 7,000 patients in the course of last year.

## Scotland.

### THE ABERDEEN HOSPITAL FOR SICK CHILDREN.

A WELL equipped pediatric department is so important a constituent of a school of medicine that the resolve of the managers and staff of the Royal Aberdeen Hospital for Sick Children to erect a new building will be universally applauded by the medical profession. Old Aberdeen graduates will know that the project is overdue. A site was secured as long ago as 1914, plans had been drawn up, and £20,000 out of the £35,000 believed at that time to be necessary for the building had been received, when the scheme had to be suspended owing to the outbreak of war. The scheme was revived in 1919, and considerable progress towards obtaining the capital sum required was made, but the cost had then advanced to £70,000. The delay has not been altogether an evil thing, because it has now been possible, with the help of the Committee of the Joint Hospitals Scheme and the goodwill of the town council, for the directors to buy a fine site at Forresterhill. But the realization of the architect's plans will, at present prices, cost £110,000, and of this amount £45,000 remains to be raised. The plans show four ward blocks, an isolation block, and x-ray and out-patient departments; the site affords space for further extension. The wards face south-east; the administration department is to be on the north side, as also the nurses' home, the front of which will, however, look to the south-east. There are only three sick children's hospitals in Scotland—two in Edinburgh, one in Glasgow, and that in Aberdeen. In the present hospital in Aberdeen 32,000 patients have been treated, and every Scottish county from Forfar to Caithness, including Orkney and the Shetland Islands, has contributed patients. The staff, through the letter signed by Mr. Alexander Mitchell, surgeon to the hospital, published at page 680, appeals to old residents and old graduates to help. Contributions, marked "Staff Fund," may be sent to Miss Hill, superintendent of the hospital.

### CAMPAIGN AGAINST RATS.

An intensive campaign against rats opened on Monday, March 30th, and is to last for a week. It has general support from local authorities, who have undertaken to supervise the operations. Railway companies and the naval and military authorities throughout Scotland have also agreed to take special action. Poisoning, trapping, gassing, and ferreting are the special means extensively practised, and a special effort is being made in connexion with public sewers, sewage works, refuse bins, and other breeding places of rats. Special attention is also paid to the rat-proofing of buildings, as regards defective ventilators, holes under doorsteps, and crevices in external masonry. As the number of rats in any locality is directly proportionate to the food supply available to them, garbage and refuse are, as far as can be, removed or destroyed, so that the maximum benefit may be derived from the campaign. It is estimated that the cost of the destructive activities of rats cost the country somewhere about fifteen millions sterling a year, and the rat is well known to be a potential danger to the public health.

### THE PROBLEM OF MALARIA.

Professor J. H. Ashworth presided over a meeting of the Royal Society of Edinburgh on March 23rd, when Dr. Andrew Balfour, C.B., C.M.G., Director of the London School of Hygiene and Tropical Medicine, gave an address on malaria, which, he said, had acquired fresh importance in this country, owing to its use as a therapeutic agent in general paralysis, and also because there was at the present

time a certain amount of danger that biology and medicine might be treated in separate, water-tight compartments. The problem of malaria demonstrated very effectively the close association between the two studies. Dr. Balfour went on to consider the question of geographical distribution with reference to the case of Scotland; the early prevalence of malaria in Scotland was described and probable reasons for its decline suggested. An anopheline mosquito still abounded in Scotland, and it was quite possible that indigenous cases of malaria still occurred. A combined mosquito and malaria survey might be useful, at all events from the scientific and academic standpoint. The reasons why malaria causes death were considered, and special emphasis was laid on the condition of liver failure, which often occurred. The influence exerted by malaria upon industry and the economic welfare of a country were also considered, as well as the curious immunity which was shown by lower animals to the parasite of human malaria. Reference was made to the introduction of stovarsol as a rival to quinine in the treatment of malaria, and in connexion with the problem of periodicity it was pointed out that, although a great deal of work had been done, the prevalence of malaria still remained a most elusive question. The lecture was illustrated by a cinematograph film supplied by the Rockefeller Foundation.

### GLASGOW CANCER HOSPITAL.

The thirty-fourth annual general meeting of subscribers to the Glasgow Cancer Hospital was held on March 23rd, under the chairmanship of Sir J. Macleod, Bt. Lord Provost Montgomery, in moving the adoption of the annual report, said that he knew no work which commended itself more to the people of the city. He believed that cases of cancer were on the increase, and greater facilities for research were required in the hospital; for this reason he appealed for increased financial support. Sir George T. Beaton, senior surgeon of the hospital, in seconding the adoption of the report, said that the primary object with which the hospital had been founded was very faithfully fulfilled, and the directors had decided that to carry on the work of research satisfactorily there should be built up a special fund of at least £20,000, which would furnish, along with Government and other grants, an income that would meet the current expenses of this department. Towards this sum nearly £12,000 had been already collected, and one donor had promised the final £1,000 as soon as £19,000 had been subscribed. The real cause of cancer was still unknown, and the disease was largely on the increase, especially in regard to cancer of the digestive canal. Nevertheless, important advances in knowledge had been made in recent years, and, thanks to anaesthetics and antiseptics, increased success attended early operative treatment. In inoperable cases valuable aids to treatment were being found in radium and deep x-ray therapy. He urged that the general public should get rid of the idea that cancer was incurable by operation, and also that it was necessarily accompanied by intense suffering, and should take a hopeful, consolatory view. Professor D. Noël Paton said that the present aim of research work was to find out the nature of cancer and its cause. The discovery of the cause might come from some small laboratory, as many discoveries had come in this way.

### VETERINARY EDUCATION IN SCOTLAND.

A protest made by the Royal Faculty of Physicians and Surgeons of Glasgow in reference to the proposed withdrawal of the Government grant from the Glasgow Veterinary College was noticed in our issue of March 21st. A further protest was made at a public meeting held in Glasgow on March 25th. The point at issue appears to be that a departmental committee on agricultural education reported that the maintenance of two veterinary colleges in Scotland was, from a purely educational point of view, unnecessary, and that in view of the relative circumstances of the two existing colleges the grant of State assistance to the Glasgow College should be discontinued. Lord Provost Montgomery presided at the meeting, and in opening the proceedings said that he regretted the proposed discontinuance of the college as an inconvenience to students. In fact, it would be impossible for

a number of students resident in the West of Scotland to attend a college in Edinburgh. Professor Glaister, chairman of the governors, in stating the case for the Glasgow College, said that the meeting could be regarded as a protest against the Government and against its administrative body, the Board of Agriculture for Scotland, in regard to its intention to extinguish an institution in Glasgow which, during sixty-five years, had been doing work in furthering the interests of veterinary science. The trend of one section of public feeling favoured the centralization of veterinary education in Edinburgh. He pointed out that, with regard to the amount of financial assistance given by the State to the Glasgow and Edinburgh Veterinary Colleges respectively, the figures were: for 1922-23 £900 and £3,000, for 1923-24 £1,000 and £3,225, and for 1924-25 the estimates were £1,037 and £3,589. Sir Charles Cleland moved a resolution protesting against the action of the Board of Agriculture for Scotland; the college was a distinct educational asset, both from its past history and from the possibilities for the future. The Education Authority of Glasgow made a contribution towards the funds of the college annually, and it seemed to the authority that it would be ridiculous to be compelled by force of circumstances to contribute a similar or larger sum to Glasgow students, who would be forced to leave their native city and seek instruction in the East of Scotland. He did not think that in a city like Glasgow the public should permit such a useful institution to close its doors. The resolution was seconded by Mr. Gavin Hamilton, Lesmahagow, Convener of the County of Lanark, who said his council unanimously supported the continuance of the college. The resolution was adopted, and it was agreed that copies should be sent to the Prime Minister, the Secretary for Scotland, and the members of Parliament for the city of Glasgow.

#### EDINBURGH DENTAL HOSPITAL AND SCHOOL.

The thirty-third annual general meeting of the Edinburgh Dental Hospital and School was held in the hospital on March 20th, under the chairmanship of Dr. William Guy, F.R.C.S. It was stated that the work done in the hospital during the past year comprised a total of 12,703 conservation cases (fillings, inlays, dressings, and sealings), 1,237 cases under prosthesis, and 19,325 extractions; 1,005 skiagrams were taken. During the year 112 students had attended, as compared with 100 in the previous year. Reference was made to the building operations for the extension of the hospital and school now in progress; the Dental Board of the United Kingdom had promised a contribution of £5,000 towards the cost of this extension and a further sum of £1,000 for equipment; the Edinburgh Town Council had made a grant of £200 per annum for five years, or £1,000 in all, towards the cost, but a further sum of £12,000 would be required to cover the cost of furnishing, equipment, etc. Dr. W. Robertson, medical officer of health for Edinburgh, who moved the adoption of the report, said that the connexion between a public health department and an institution like the Dental Hospital was very close. Nearly all the ills that flesh was heir to were traceable to bad digestion, and if the teeth were properly attended to the people would not only be healthier, but also more contented.

## Ireland.

#### ULSTER MEDICAL SOCIETY.

A MEETING of the Ulster Medical Society was held in the Medical Institute, Belfast, on March 19th, to hear an address from Lieut.-Colonel L. W. Harrison, D.S.O., M.B., director of the V.D. Clinic, St. Thomas's Hospital, London, and to witness a cinematograph demonstration of the diagnosis and treatment of gonorrhoea. Dr. Cahill, vice-president, was in the chair in the absence of Dr. Darling, who, a few days earlier, had met with a motor accident. His car overturned, and though he suffered no serious injury he was confined to bed for a short time; when allowed to get up he was not able at once to return

to full work. Colonel Harrison gave a clear and illuminating exposition, which was closely followed by all present and much appreciated. Professor Fullerton proposed, and Professor Lindsay seconded, a very hearty and warm vote of thanks on behalf of the society to Colonel Harrison, which was passed with acclamation.

#### ROYAL VICTORIA HOSPITAL, BELFAST.

The annual meeting of the Royal Victoria Hospital, Belfast, was held in the King Edward Memorial Hall on March 23rd, when the one hundred and thirty-second annual report of the board of management was presented. Lord Londonderry presided, and there was a large attendance. The financial statement showed an income of £53,914, and an expenditure of £54,424; this small deficit was considered most satisfactory having regard to the abnormal conditions prevailing. The hospital, it was pointed out, owed a deep debt of gratitude to their financial authorities, and to the superintendent (Colonel Forrest), the matron (Miss Musson), and all who worked so diligently for the welfare of the institution. The cost of each occupied bed was £140 a year. The expenditure on the new buildings and wards and their equipment would be £120,000, and an additional income of £11,000 a year would be required for upkeep. This was a serious responsibility, but the board was determined to keep the hospital thoroughly up to date and worthy of the town and province. The chairman referred with great satisfaction to the magnificent response of the workpeople, which amounted to nearly £20,000 for 1924, and to the noble bequest of the late Mr. Musgrave, some £56,000. Mr. Mitchell, chairman of the medical staff, proposed, and Dr. Morrow seconded, the adoption of the medical report, which stated that the numbers in all departments were increasing; the waiting list still grew in spite of all efforts to provide adequate accommodation. In addition to the medical students there were now twenty-five dental students; the new dental department was in full swing and doing an immense amount of good. Twenty-four probationers had entered and passed the first preliminary State examination for the registration of nurses. The board had, on the recommendation of the medical staff, increased both the permanent and the auxiliary staff again and again; the pathological, biochemical, and radiological departments were all working at high pressure. A body of young volunteer adults had now been organized throughout the town, who were now tested and ready to give their blood when transfusion was required. After much routine business had been transacted, the chairman of the board of management, Professor Lindsay, who was elected chairman for the seventh year in succession, proposed a hearty vote of thanks to Lord Londonderry, which was carried by acclamation.

#### MAINTENANCE OF DUBLIN HOSPITALS.

That the imposition of a tax for the upkeep of hospitals on people who could afford to give was a proposition worth considering, was the declaration of the Provost of Trinity College, Dublin (the Most Rev. Dr. Bernard), at the annual meeting of the Royal Victoria Eye and Ear Hospital. He did not, he said, believe the deficit in the accounts of the hospital could be made up by an increase in voluntary subscriptions. He was not sure that the time had not come for some kind of tax to be imposed upon the public for the upkeep of institutions of that kind. How, he asked, were they to pick out the people who were best able to give? The people who went to the theatre? Entertainment tax was put upon them. People who kept motor cars? If a person was able to keep a motor car, he or she ought to be able to pay something for the upkeep of the great hospitals of Dublin. The Eye and Ear Hospital was a national institution; its work was not confined to Dublin, and consequently it should appeal to the public in a way in which a local hospital, however good, could not. The report states that 1,702 patients were admitted and occupied beds for a period equal to 29,593 days, giving an average of 89.52 beds occupied daily. In the out-patient department 8,119 new patients were registered and 3,256 attended for further treatment, making a total of 11,375. The total ordinary income for the year was £7,980, and

fell short of expenditure by £2,836. Legacies received during the year had to be allocated to the current account instead of to capital, with the result that unless some great reduction was made in ordinary expenditure, or some great addition to ordinary income, the overdraft would be very heavy. A comparison with the previous year showed a reduction of nearly £2,000 in income. The bequests amounted to £900. In moving the adoption of the report, Sir George Roche, president of the hospital, said that for the previous year the deficiency was only £63 odd, while for the past year it had increased to £1,553. He was sure that when that fact was brought home to the charitable Irish public the hospital would not appeal in vain. The figures quoted in the report showed the splendid voluntary work that had been done by the medical staff of the hospital, and that was all the more surprising when the smallness of the staff was considered. Supporters had learnt with pleasure that recently an order had been made by one of the judges declaring that the hospital was entitled to the fund available under the terms of the will of the late Mrs. Harvey Lewis, amounting, he thought, to £21,000; this, he hoped, would enable an additional wing to be built and equipped with forty beds. Chief Justice Kennedy, in seconding, said the report was extremely creditable; the accounts ought to appeal to everyone who read them as an incentive to do something to help the enthusiastic band who were carrying on the great work of the hospital.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has this week advanced a number of Government bills, including the Housing Bill, Housing (Scotland) Bill, and Town Planning Bill—three codifying measures which received second reading on March 31st. A debate arose that evening on accidents in mines, with special allusion to the Scotswood pit disaster. A resolution calling for legislation to strengthen the provisions of the Coal Mines Act, 1911, was carried without a division, and in view of the sympathetic attitude of all parties such legislation seems probable. There have also been debates on unemployment and on the British Empire Exhibition. The House of Lords has rejected Lord Banbury's Dogs Protection Bill.

#### Penalties on Doctors.

##### *Minister of Health's Defence.*

Mr. Herbert Williams asked the Minister of Health, on March 26th, why penalties of £10 and £20 respectively were imposed on two doctors who had been accused by the London Insurance Committee of gross negligence in cases of appendicitis and diphtheria respectively, but had been found innocent by a committee appointed by the Ministry of Health. Mr. Neville Chamberlain replied that misapprehension had arisen regarding these cases. The death of two insured persons in London in 1924 led to complaints being lodged with the London Insurance Committee in regard to the treatment received by them from the two insurance practitioners concerned. These complaints were investigated by the Medical Service Subcommittee of the Insurance Committee, which, with the concurrence of its medical members, recommended that in both cases a substantial deduction should be made from the doctors' remuneration. The Insurance Committee itself, however, regarded the cases as cases of gross negligence, and accordingly made representations to the Minister of Health, under the Regulations, for the removal of both doctors from the medical list. These representations necessitated the appointment of an Inquiry Committee. That Committee, consisting of a barrister and two medical practitioners, found that the allegation of "gross" negligence was not established in either case, but their findings of fact indicated that in one case the doctor had failed to exercise reasonable care, and that in the other case the doctor had failed to respond to a request to visit the patient at what proved to be a critical period in the illness. After careful consideration of the reports of the Committee he (Mr. Chamberlain) came to the conclusion that, while the facts established were not such as to warrant the removal of either practitioner from the medical list, there was abundant ground for the original recommendation of the Medical Service Subcommittee that grant should be withheld. There was no ground for the statement that the practitioners were found innocent. The procedure followed in these cases presented no exceptional features, but followed the practice of the Insurance Commissioners and of previous Ministers of Health.

#### Dogs Protection Bill.

In the House of Lords, on March 31st, Lord Banbury moved the second reading of the Dogs Protection Bill, which had been rejected by the House last year. He cited an opinion of the late Sir Lambert Ormsby that all that could be found out by physiological experiment of value to man had been discovered, and adduced letters from Sir William Collins and Dr. Nash which, he said, were in favour of his bill. He said that Sir Frederick Treves had declared that in dealing with man he had been hampered by prior experiments on the intestines of dogs. Lord Banbury said that when applying for licences for operations on horses, mules, and asses the applicant had to state that the operation could not be performed on any other animal. If anaesthetics were to be employed no such declaration was necessary for a licensee to operate on dogs. Would Lord Knutsford agree to an amendment making such a declaration requisite? Two contradictory certificates were employed—one saying that the animal must be killed if the object of the experiment had been secured, the other that it must be killed if suffering severe pain or pain likely to endure. There were only two inspectors; how could they be present at any number of these operations? If not, who could be the judge of "severe pain" except the operator? The only protection which a dog had was the Act of 1885, as interpreted by the Home Secretary. He thought that the Act should itself lay down the conditions of experiment. He concluded by quoting an epitaph written by Lord Byron on a dog.

Lord Knutsford said he was told that since 1819 no motion for rejection of a bill had been allowed in that House, so he was compelled to move that it be read in a year's time. If this bill were to be brought in every year it would show that Lord Banbury's mind was not open to argument. He suggested that the stereotyped arguments for and against should be recorded for the gramophone so that they could enjoy them in the tea-room without wasting the time of the House. This was not a bill dealing with the question whether experiments should be allowed on animals, but whether dogs should be used for experiment. If the bill passed no experiment could be made on any dog, not even a feeding experiment to get rid of distemper. The whole physiological process of a dog was nearer to that of man than that of any other animal, except perhaps a monkey, and the whole medical and surgical world had never been so unanimous before as against this bill. The Royal College of Surgeons had declared that the bill would retard progress. Was that the attraction to Lord Banbury? Was there a subconscious awakening of his old instinct of obstruction? Other medical and surgical bodies had passed similar resolutions, and the Medical Research Council of the Privy Council had recorded its belief that the passage of the bill would put insuperable barriers in the way of some lines of research. Lord Curzon, when the bill was last before the House, had said that the scientific men of Oxford were against the bill, and the Royal Commission on Vivisection, from whom Lord Banbury had the hardihood to quote, had actually included dogs as suitable for experiment under the same conditions as horses. All were unwilling to use the dog, but recognized that it had to be done. The dictum of the late Sir L. Ormsby which had been quoted by Lord Banbury could not have been upheld had Sir Lambert lived till 1925, when insulin had been discovered and fresh discoveries were being made every day. The medical world did not deal with politics, and it was worthy of respect when it spoke unanimously on a subject such as this. Had the decision of the House last year been justified? Insulin had stood the test of time. Diabetes was no longer a sentence of death on boys and girls nor an intolerable burden on adults. That mitigation was entirely due to experiments on dogs. There were many other instances. During the past year progress had been made with the researches on distemper. Were experiments to be permitted to cure distemper, but not in the hope of saving human life? If there was a chance of benefiting mankind it seemed to him gross cruelty to refrain from gaining knowledge. England would be the laughing-stock of the whole world if it were to reject the opportunity to reduce suffering by research.

Lord Lambourne said he hoped to live to see two things: corporal punishment for offences against young children, and protection for the living body of the dog. The majority of experiments on the dog had been useless. There was no desire to hinder the greatest profession of the world. The objections of Lord Knutsford had been advanced to all previous Vivisection Acts, but despite the passage of those Acts had our surgeons fallen behind those of other countries in skill? The House of Commons would look upon such a bill as this with more favour at present than it had done for some time past.

Lord Mildmay confessed to astonishment that Lord Banbury had again ventured to bring forward this bill. He resented the implied imputation that opponents of the bill were inhumane. If he thought that those conducting research work were guilty of cruelty he would be up in arms in defence of the dog, but he thought that the campaign in favour of the bill had been conducted outside the House by unverified assertions and mere abuse. As the only member of the Medical Research Council in the House it was his duty to convey the opinion of that body. Its members authorized him to make known how strong and unalterable was their opposition to the bill as likely to impede the progress of medical science and the prevention of disease. The all-important discovery that rickets was a dietetic disease controllable irrespective of sunlight was entirely due to experiments on dogs. A short time ago one child in ten in the great cities suffered from rickets. Now it was reported to the Medical Research Council that a child so suffering could scarcely be found in London. He opposed the bill in the interests of dogs themselves. At the Medical Research Council's research farm at Mill Hill they were investigating the scourge of distemper. Were these experiments to be arrested, as they would be if the bill passed? The filter-passing agent of distemper was closely akin to the agent of influenza, and research into

animal and human disease could not be separated. The research was making progress, but results could not be announced till the third generation of immune puppies had been produced. Filter-passing agents were being attacked from many quarters with good promise of success, and success in one direction would lead to results, not only in foot-and-mouth disease, but, in influenza, chicken-pox, and possibly rheumatism. In his association with those engaged in medical research he had been impressed by their real beauty of character, and he felt compelled to speak his admiration of the way they worked for the one object of diminishing pain and suffering. To describe them as "meddling in entrails with blood-stained fingers" was blasphemy. The physiologists were steadily reducing suffering in men, women, children, and animals.

Lord Rayleigh said the people who did research were a small minority of the medical profession, and so far as he could learn none of the medical men cited by Lord Banbury a year ago in support of his case had ever made any discoveries.

Lord Buckmaster said Lord Knutsford had spoken with an authority gained by a life unstintingly devoted to the noblest of causes. He spoke as a man keenly anxious to consider whether in the interest of humanity existing laws needed to be modified. Lord Banbury had not laid before them new grounds to justify bringing forward his bill again so soon. He had not presented a new argument or a new fact. Lord Banbury had not ventured to contradict the assertion that diabetes and rickets had been countered by experiments on dogs. The bill's real appeal was to people who objected to vivisection altogether. He asked the House to reject the bill so emphatically that they would not be troubled with it again.

Speaking for the Home Office, Lord Desborough said it was not opposed to this bill now as it had been last year.

The bill was rejected by 77 votes to 8.

### Summer Time Bill.

In Standing Committee on the Summer Time Bill, on March 25th, Sir Henry Cantley moved an amendment to make summer time commence in future years as at present. Colonel Lambert Ward, in opposing the amendment, quoted the following passage from a letter from Sir Henry Gauvain: "It is not generally appreciated that towards the end of the winter many children are suffering from what may be termed shortly 'light hunger.' It is the spring light in the morning hours, when the air is clear and cool, and the heat rays are as yet unable to exercise their antagonistic action, that is especially therapeutically valuable."

The amendment was rejected, and the bill was reported to the House without amendment.

### Pensions.

**Late Development of Disability.**—In reply to Mr. Stephen, on March 26th, Colonel Stanley said that the Minister of Pensions had seen no evidence to justify the suggestion that the seven years' limit for lodging claims by ex-service men for pension should be removed. This time limit had been embodied in the War Pensions Act of 1921 in accordance with medical advice. The Ministry was not getting many complaints about the limit. Mr. Beckett asked whether there were not many disabilities, such as heart trouble, which did not show when a man was young, but at a later age. Colonel Stanley replied that the period had been put at seven years because the medical advisers to the Ministry considered that any such complaint would show itself within seven years. Answering a further question on the same day, the Prime Minister said that the Government was not aware of any grounds to justify the appointment of a Select Committee to inquire into the whole question of war pensions and the machinery of administration of the Ministry of Pensions. It would not be a good thing if so complicated a matter as a Royal Warrant were to be subjected to special investigation at frequent intervals.

**Medical Treatment.**—Mr. Groves asked the Minister of Pensions, on March 25th, whether his attention had been called to the position of numerous disabled ex-service men who, on applying for treatment and being examined by the medical referee of the Ministry, were decided to be unfit in consequence of their pensionable disability, but were advised that their treatment should be from their ordinary panel practitioner instead of from the Ministry; whether he was aware that these ex-service men, although decided to be unfit for work, did not receive any treatment allowances, although they might be out of benefit so far as national health insurance was concerned, and that they were therefore compelled to apply for parish relief or charitable assistance; and whether, in virtue of the fact that the Royal Warrant expressly stated that men certified as being in need of treatment would be provided with it at the expense of the Ministry and receive the appropriate allowance, he would cause investigation to be held respecting the present procedure. The Minister replied that Mr. Groves was under some misapprehension as to the provisions of the Royal Warrant. Article 6 of that Warrant empowered the Minister to grant special allowances only in those cases where a disabled man was certified to need a specific course of treatment in consequence of which he would be rendered incapable of supporting himself and his family. The conditions governing the grant of allowances under Article 6 of the Warrant were not identical with those which determined certification for the purpose of sickness benefit under the National Health Insurance Acts, and it was not the function of the medical officers of the Ministry to determine generally whether a disabled man was fit for work or not. The Ministry's information was that the intentions of the Royal Warrant were being carried out.

**Tuberculosis.**—The Minister of Pensions informed Mr. Groves, on March 26th, that ex-service men suffering from pulmonary tuberculosis or diabetes mellitus could still receive under the Pensions Regulations, if the circumstances required it, additional allowances in the form of special diet, provided that the pension was not at the maximum rate.

**Final Awards.**—The gross number of final awards for officers and men declared up to the end of February is 478,098. Under Circular 30 the Ministry has dealt with 416 cases on the ground of serious errors of diagnosis or of prognosis. At present 247,800 final awards of life pensions and 264,200 conditional pensions are in issue from the Ministry of Pensions.

**Medical Staff.**—It is intended to recommend forty-eight of the existing whole-time medical staff of the Ministry of Pensions for permanent appointments, but no such appointments have yet been made. The successful candidates will enter on their new posts at their existing rates of pay, subject in a few cases to slight adjustments up or down.

### Tuberculosis.

**Segregation.**—Colonel Day asked the Minister of Health, on March 26th, to consider appointing a court of inquiry to investigate and report on the prevailing conditions of the public health service of the country, and to inquire especially into the compulsory segregation of persons seriously affected with tuberculosis and in an infectious and incurable condition. Mr. Neville Chamberlain replied that as at present advised he saw no necessity for such an inquiry. Legislation on the compulsory segregation of persons suffering from tuberculosis and in an infectious condition had already been obtained by a number of local authorities, and possibly, as suggested by the Local Legislation Committee, an opportunity for dealing generally with the matter might be found on the Public Health Bill which the House had read a second time. Colonel Day further asked whether the Minister would take steps to provide protection to children and near relatives who, through lack of housing accommodation, were forced to live in close proximity to persons seriously affected with tuberculosis. Mr. Neville Chamberlain replied that it was for the local sanitary authorities to take all practicable steps to prevent the spread of infection.

**Institutional Treatment.**—Mr. W. C. Robinson asked what increased provision had been made for the treatment of tuberculosis in England since the issue of the circular of February 8th, 1924. Mr. Chamberlain replied that since then the provision of more than 1,300 additional beds had been approved. Local authorities had been authorized also to take additional beds at institutions belonging to voluntary bodies and to carry out other developments of their tuberculosis schemes. The number of persons under treatment for tuberculosis in residential institutions had increased by nearly 1,300 since February 1st, 1924. The net expenditure on tuberculosis by local authorities which was about to be sanctioned for 1925-6 was £100,000 in excess of the estimated net expenditure for 1924-5.

**Finance: Insurance Reserve Fund.**—Asked by Major Wheler and Mr. Bennett, on March 26th, why it was necessary to have so large a sum as £100,000,000 in reserve for England alone under the National Health Insurance Act, the Minister of Health said that liabilities under national health insurance increased with the age of the insured persons, while the contributions were fixed in all cases from 16 to 70, and were actuarially calculated to suffice for a person entering into insurance at 16. Whether funds had accumulated in excess of requirements was determined by the quinquennial valuations made under the Act. At the last valuation over £6,000,000 of surplus funds was distributed in additional benefits, and a considerably greater distribution was expected from the valuation now in progress. He thought that the reserve was still increasing, but the surplus from the last valuation would not be anything like £30,000,000.

**Poison Gas Experiments.**—Mr. Ammon asked the Prime Minister, on March 26th, if he would set up a public committee to inquire into the practice of subjecting young soldiers to the effects of poison gases for experimental purposes at the chemical warfare research department. The Financial Secretary to the War Office, Captain King, replied that there was no need for a public committee of inquiry. The conditions of the exposure of personnel to gas were carefully regulated in accordance with the best medical and scientific advice, and the experiments were made under the direction of medical officers. In answer to further questions, on March 31st, the Secretary for War said that 372 experiments with poison gas on human subjects had been made since 1918, and 188 soldiers were engaged in them. All volunteered for this special duty, and none suffered injury to the lungs or otherwise through being subjected to these tests. The experiments comprised exposures to low concentrations of gases to ascertain their physiological properties; exposure to gas of personnel protected by respirators; and tests on the human skin of new compounds to ascertain their irritant action, if any. All such experiments had been carried out under most stringent regulations, framed on the best medical advice obtainable to safeguard the health of those concerned.

**Factories Bill.**—Asked by Lord Henry Cavendish-Bentinck, on March 25th, whether the Government intended to pass the Factories Bill into law this session, the Home Secretary did not answer the question directly, but said that he must have further interviews and consultations before he could submit the proposed bill to the Cabinet, but he hoped shortly to be able to do so. (In a published statement the Home Secretary indicated that in the present depressed state of British trade he could not be responsible for

any legislation which would further reduce production and employment.) In an answer on March 26th, the Home Secretary said that one of the clauses of the Factories Bill was for bringing all workshops into the category of factories.

**Declarations of Objection to Vaccination.**—Mr. T. Thomson asked the Home Secretary, on March 26th, whether certain magistrates refused to witness statutory declarations under the Vaccination Act, 1907; and whether, following the precedent of one of his predecessors, he would address a circular to all magistrates, calling their attention to the legal obligations upon them to witness statutory declarations when sitting in open court, and pointing out to them that they are neither required nor authorized to cross-examine applicants as to the reason of their objection to vaccination. The Home Secretary replied that on March 17th he received a deputation from the National Anti-Vaccination League, which made representations on the subject. He would consider the question of issuing a circular when he had received and examined further particulars which he had asked the deputation to furnish.

**Preservatives in Food.**—In reply to a question, on March 25th, Sir Kingsley Wood, for the Minister of Health, said that the effect of the draft regulations of March 17th dealing with preservatives in foods was that all coal-tar colours which were not included in the schedule might be used in food till they were shown to be injurious to health. Although lead and arsenic were present in coal-tar products, the Minister was advised that the percentage of these substances liable to be introduced thereby into foodstuffs was so minute that it was unnecessary to extend the regulations by laying down the quantities of lead and arsenic permitted in such coal-tar compounds. He had arranged to receive a deputation from the confectionery, bakery, and allied trades with regard to the draft regulations. The scientific evidence on the effect of boric acid was thoroughly considered by the Departmental Committee on Preservatives in Food. Mr. Goodman Roberts, on March 30th, asked the Minister of Health whether he had any evidence that the small quantity of boron preservatives permitted to be used in liquid eggs was deleterious to health; whether it had been decided to prohibit this use of boron preservatives; and whether, before issuing regulations, he would consider the probable increased cost of important foodstuffs into which eggs enter, seeing that there was no adequate provision for cold storage in this country to make cold-storage eggs a practical substitute for liquid eggs. The Minister said that the Departmental Committee on Preservatives in Food was unanimously of opinion that boron preservatives were so harmful as to justify total prohibition. Before the final form of the regulations was settled full weight would be given to such considerations as Mr. Goodman Roberts mentioned.

#### Notes in Brief.

The Geneva International Labour Conference has decided against the inclusion of a draft convention on anthrax on its agenda, and the Home Secretary considers that nothing will be gained by a further attempt of the British Government to reopen the question.

Since the issue of the circular of February 8th, 1924, the number of maternity and child welfare centres in England and Wales has increased from 1,986 to 2,112. Proposals for about 30 additional centres are under consideration. Sessions for infant consultation, ante-natal work, and the like have been provided at 95 existing centres.

In 1924 £5,359,953 was paid as domiciliary poor relief to persons ordinarily engaged in some regular occupation and to their dependants. In the financial year 1924-5 the State paid £53,818,800 on health insurance, unemployment insurance, old age pensions, and unemployment grants. The charge for health insurance was £8,045,760.

From January 1st, 1924, to March 26th, 1925, 260 soldiers were discharged from the army for tuberculous disease.

The Prime Minister has announced that the Government has under careful consideration the statement of the Secretary for War that 5 out of every 8 recruits for the army are rejected as physically unfit.

The Royal Commission on Lunacy and Mental Disorder hopes to be able to present its report early next year.

Special provision is made, the President of the Board of Education announces, for the vocational training of students from special schools for defective children.

Deaths from malaria in India are included in the returns under the general heading of deaths from fever. In 1922 these were 3,600,000, of which a very large proportion were undoubtedly due to malaria. Recent reports showed that the desirability of attacking the breeding places of the mosquito was fully realized by the health authorities of the Provincial Governments, but the difficulties in the way of effective measures on a large scale were enormous.

The Minister of Agriculture informed Dr. Fremantle, on March 30th, that he has no power to arrange for the supply of the specific vaccine and serum for the prevention of pig erysipelas, which at present is only available from the Continent.

The Minister of Health does not consider it necessary to put on the Nursing Council the additional burden of issuing to registered nurses a detailed account of the moneys (approximating to £60,000) paid by them for the administration of the Act. An audited statement of accounts is issued annually.

In a question put on March 30th, Mr. Oliver suggested that 20 per cent. of the men employed in a certain factory were, in the week ending March 7th, affected with a complaint known as acetone gastritis. The Home Secretary states that the matter is being investigated.

## Correspondence.

### HEREDITY AND TUBERCULOSIS.

SIR,—In a leading article in your issue of March 14th (p. 517) you commented upon the opposing results obtained by Professor Raymond Pearl and Mr. G. J. Drolet in recent American researches into the hereditary factor in tuberculosis. If I may briefly recapitulate, the preliminary results of Professor Pearl's study of the family histories of tuberculous and non-tuberculous persons showed 8.9 per cent. of tuberculosis in the parental generation of the tuberculous, as compared with 1.8 per cent. in the parental generation of the non-tuberculous, figures which are at least consistent with the view that the hereditary factor is a real one. On the other hand, Mr. Drolet, in comparing the family histories of 2,605 tuberculous adults with those of 1,638 non-tuberculous adults, found rates of 12 and 13 per cent. respectively in the "preceding generation," which he defines in a footnote as "parents, grandparents, occasional aunt or uncle." I am quoting from Tables 2 and 3 on page 285 of his paper,<sup>1</sup> as this method of treatment, though open to criticism, brings out better the contrast with Professor Pearl's results. In the case of children the corresponding percentages were 42 for the tuberculous and 63 for the non-tuberculous.

In your article you urge that a fuller analysis of Mr. Drolet's material should be prepared before accepting his views regarding the hereditary factor, but as you do not suggest wherein the real fallacy lies, except that it may be in the accuracy of the family histories, I venture to do so, since the matter at issue is of considerable importance. It appears to me at once evident on reading Mr. Drolet's paper that the whole fallacy lies in the selection of his "non-tuberculous patients." As I understand the paper, these were all cases examined at the Bellevue Tuberculosis Dispensary, and found to be non-tuberculous; thus, in a footnote to Table 3, we are told that the material relating to these 2,509 patients was "compiled from the histories of all the non-tuberculous cases examined at the Tuberculosis Clinic of Bellevue Hospital, New York City, during the years 1913, 1914, and 1915." On page 281 Mr. Drolet says, "In the non-tuberculous part of the population examined in dispensaries, an ideal control group is available." My own view would be that for the purpose of studying the hereditary factor, no control group could possibly be more inadequate, for the obvious question arises—What are these non-tuberculous patients doing at a tuberculosis dispensary at all? Speaking from only a slight knowledge of tuberculosis dispensaries, I venture to suggest that the great bulk of the cases which appear on their books as non-tuberculous may be roughly placed into three groups:

1. Persons who have been expressly requested to attend the dispensary for examination by the medical officer or his staff of nurses because a parent, child, or sibling has been found to be tuberculous.
2. Persons who have come of their own choice, or, in the case of children, have been brought by their parents because they were nervous about their health, owing to a parent, child, or sibling being known to be tuberculous or to have died of the disease.
3. Persons sent by medical practitioners or coming on their own account for confirmation or otherwise of a suspicion of tuberculosis.

I should further judge, though I am prepared for contradiction by those who are better able to form an opinion, that for children under 16 these three groups would be roughly equal in size. If so, and the same conditions hold good in the American dispensaries, we should have to conclude that two-thirds of Mr. Drolet's "ideal control group" of non-tuberculous children had been in reality selected for the very reason that they had a near relative tuberculous! It is not surprising, therefore, that 63 per cent. of these children gave a history of tuberculosis in the preceding generation, and 12 per cent. more had a

<sup>1</sup> *American Review of Tuberculosis*, November, 1924, x, No. 3, pp. 280-288.

brother or sister affected. In the case of adults the first two groups would be relatively smaller and the effect of selection correspondingly less, but nevertheless sufficiently large, I believe, to account for most of the discrepancy between the 13 to 14 per cent. with parental tuberculosis and Professor Pearl's figure of 1.8 per cent.

Possibly I have overstated the case, but even so it must be evident that no quantitative conclusions whatever can be reached regarding the hereditary factor from a study of non-tuberculous patients on the books of a tuberculosis dispensary unless we are able to analyse exactly the reasons which brought them there. I may say that we have found the analysis of records of a tuberculosis dispensary in Great Britain, not as yet completed, to lead to very similar percentages to those found by Mr. Drolet, but the non-tuberculous patients have been regarded as useless for a control group in assessing the hereditary factor for the reasons I have given. Professor Pearl's control group was not, I think, open to these objections.—I am, etc.,

PENNY STOCKS.

Department of Applied Statistics, University  
College, London, W.C.1, March 26th.

\*. The considerations adduced by Dr. Stocks emphasize the caution we gave; but whether even these suffice to account for the apparent excess of tuberculosis in the descendants of the non-tuberculous, whether there is not some other peculiarity of the material, can only be determined after the fuller analysis which, in our view, should be published.

#### THE TREATMENT OF PNEUMOCOCCAL EMPYEMA.

SM.—I think it is possible that a faulty impression of the value of the "suction method" for the treatment of empyema devised by Mr. F. Reynolds, and described by us in the *Lancet* (1921, ii, 1109), may be given by Mr. Hathaway in his letter in your issue of March 28th (p. 632). This I should like to correct, because I believe it to be a method which careful trial and study will prove to be of real value. At present it cannot be claimed that it has been thoroughly evolved, but in my experience fibrinous masses have not proved an obstacle, for they have in our cases gradually melted away. That the cannula may be blocked at times is certain, but this can be easily corrected, as stated in our paper.

There is one difficulty, only to be overcome by careful observation, and this is the interpretation of the physical signs in the chest when the drainage is in progress, upon which must largely turn the indication for withdrawing the cannula. These signs differ from those found in the open method, and I submit can only be gauged by making exact notes and also by noting the reasons for doubt when the removal of the cannula is in question. In finding one's way forward there must be at first hesitation, and in one case we resected later we found the cavity well drained and the operation unneeded. In another, in which I was in doubt, but resection was not done, the patient died from a pneumococcal meningitis, and here again the cavity was thoroughly drained. It is my belief that the problem of the removal of the cannula will prove to be no more difficult than it is in the open cases, when the physical signs have been thoroughly established. The difficulties in keeping the cannula from slipping out are those of technique, and I believe such are always surmounted, given the determination and the asset of skilled nursing.

The advantages are great: the avoidance of a considerable operation, the rapid recovery, the absence of nerve-racking dressings for the child are sufficient in themselves. Some cases will be unsuitable, but many more are suitable for this method. At present hospital supervision is probably needful, and there is a very rightful suspicion of dealing with pus in the chest, except by opening the cavity and drainage, founded upon the fear of leaving a hidden pocket; but my experience leads me to believe that the method is one of real value and deserving of careful trial and that failure is not dependent upon the occurrence of thick lymph.—I am, etc.,

F. JOHN PONTON, M.D.,  
F.R.C.P.Lond.

London, W.1, March 29th.

#### THE IMMEDIATE AND REMOTE EFFECTS OF SUNLIGHT ON THE EPIDERMIS.

SM.—In reference to Sir Lenthal Cheate's interesting letter in the *JOURNAL* of March 28th (p. 631), may I point out that O. Bernhard of St. Moritz, in his excellent book *Sonnenlichtbehandlungen in der Chirurgie*, says that he has never seen a case of epithelioma of the face, or hands, in the guides, drivers, postillions, and postmen, who are constantly exposed in the Alpine passes to intense sun radiation with reflection from ice and snow. The ultra-violet rays are very strong in the Alpine heights; our method of measurement by bleaching of acetone methylene blue gave a reading at Leysin of 41 on one sunny day, against 23, the highest reading obtained at Peppard Common Sanatorium by Dr. Paul Tozer last summer; 5 is his highest reading so far for a sunny day this month.

Bernhard ascribes gardener's epithelioma to dirt and chemical irritation, which, he says, causes eczema. So, too, with seaman's cancer, which, I believe, has become rare since the giving up of sailing ships and of the use of tar. If there were danger of ultra-violet radiation causing cancer, as x rays have done, the operators and patients in such institutes as the Finsen would have shown this by now.—I am, etc.,

London, N.W.3, March 30th.

LEONARD HILL.

#### THE THYROID AND MANGANESE TREATMENT IN VARIOUS DISEASES.

SM.—I had the privilege of being acquainted with Dr. Nott's methods, and of making trial thereof, before publication of his able article in your issue of March 7th (p. 443). The great interest of his practice is indicated in your leader of the same date, and in your note of March 14th (p. 520) upon the prescription of manganese.

Exactly how this drug acts would appear to be still matter for speculation altogether too deep for the ordinary clinician, who will probably accept, in seeking an explanation of the end-results, the simple summing up of one practical authority who wrote in answer to my appeal for guidance on the point: "All we know about manganese is that it appears to have the property of 'activating' other elements such as iron. Why such a comparatively small quantity of manganese has so vigorous an action we are unable to find out."

Regarding manganese just as an "activator" makes it easier to form from analogy some idea of the enhanced antitoxic action in the blood of certain endocrine secretions and inorganic bases which results from its presence, for it would seem that the combined treatment advocated by Nott is capable of giving effects which either thyroid or parathyroid, with or without calcium, do not.

The cases which have interested me most are those in which a toxæmia is presumed to have occurred through the intestinal tract, especially those of rheumatoid arthritis in which the usual patent sites of infective foci were drawn blank. The discharge of casts and shreds in some of them, followed by advance in general well-being and improvement in affected joints, even when such joints looked almost hopeless from clinical and x-ray examination, is most striking.

I find it difficult to accept the explanation suggested in your prescription note that these casts are caused by the action of caustic alkali formed during the decomposition of the permanganate. Their discharge does not go on repeatedly with the injections; it seems to take place after a few days of the treatment, and is not continuous. The impression given is rather that some drastic clearing up of a catarrhal mucous membrane has occurred, and if we assume that manganese, like excess of iron, is excreted through the intestinal mucous membrane, then may it not be that the manganese, during the process of excretion "activates" the catarrhal cells to such effect that they recover from this condition and become once more capable of acting as an efficient barrier against the passage of both organized and unorganized toxins from the bowel? It would be of interest to have expert evidence of how manganese exactly is excreted from the system.

This line of argument suggests another point to all interested in spa treatment. Various theories have been

advanced to account for the superior action of natural medicinal waters over imitations containing their chief ingredients compounded in the laboratory—radio-activity, for instance. Since the effective dose of manganese is apparently very small, it may be that the presence of this element in such waters is of more importance than has hitherto been thought, especially if shown to be in greater amount than in ordinary water supplies. All the Cheltenham springs (the Fieldholme, Pitville, Lansdown, and the Chadnor) contain manganous sulphate or carbonate.—I am, etc.,

J. S. KELLETT SMITH, F.R.C.S.,  
D.M.R.E.

Cheltenham, March 16th.

#### TREATMENT OF DIABETES BY RAW FRESH GLAND (PANCREAS).

SIR,—Dr. Hollins's paper in the BRITISH MEDICAL JOURNAL of March 14th (p. 503) led me to try feeding the raw pancreas to a diabetic under my care in the Rutland County Hospital.

The patient, a youth aged 21, is a member of a "diabetic family," in which numerous deaths from diabetes have been traced, including a brother and sister. The patient could only deal with  $1\frac{1}{2}$  oz. of starchy food; anything more was followed by sugar in the urine. On March 14th I ordered raw pancreas and gradually modified the diet, until now he is on full ordinary diet (bread, potatoes, milk puddings), and there is not a trace of sugar in the urine. The matron told me that a gland (cost 8d.) was enough for four days' treatment. The patient is now at home and his mother has no difficulty in preparing the gland.

To my mind Dr. Hollins's discovery is of even greater practical importance than that of insulin, as it brings the treatment within the range of the mass of people, whereas insulin was only for the few.—I am, etc.,

Uppingham, March 24th.

WILLIAM DUNN.

#### LIME JUICE AND LEMON JUICE FOR PREVENTION OF SCURVY.

SIR,—Rear-Admiral Sir P. W. Bassett-Smith (JOURNAL, February 21st, p. 385) has evolved a method whereby an efficient and easily portable antiscorbutic capable of keeping its properties over a number of years can be prepared. From my own point of view his work is chiefly of interest from its value to polar exploration, but it has a much wider application.

Scurvy as a fully developed disease is rare in this country. Numerous cases occurred during the war amongst populations whose food had to be found by the British. A large number were seen during the campaign in North Russia. Some occurred amongst our own troops, but in the early stages—that is, what might be called the prescorbutic stage. They were not always recognized owing to the vagueness of symptoms and absence of well marked signs. The symptoms consisted chiefly of tiredness and lethargy, for which the victim was at a loss to account. The condition, as those who have suffered from it know, is a very real one, those affected being quite incapable of sustained effort, either mental or physical, and for all practical purposes are rendered *hors de combat*. McCarrison and others have shown that in this prescorbutic stage there are marked changes in the gastro-intestinal tract and in the endocrine glands. The cases I saw, both the early and fully developed conditions, cleared up readily when active antiscorbutic vitamin was added to the ration. The lemon juice as supplied to the troops proved quite effective, but was by no means easily portable, readily froze, causing the jars in which it was contained to break, and was so intensely bitter that the men could scarcely be induced to take it. It is probable that in other places and on other occasions numerous cases of scurvy in the prescorbutic stage occurred which were not recognized, but would have been prevented by routine use of an efficient antiscorbutic. The value of a portable and palatable preparation such as that in question cannot be doubted for use in military campaigns, where relief is required for destitute populations, for cruises such as that of the

Discovery about to be carried out under the auspices of the Colonial Office, and for polar expeditions. The trouble at present is to obtain the concentrated preparation, since the demand is small and firms will not put down an expensive plant where only limited quantities of the product are required; consequently the adoption of such a preparation by the Admiralty or the War Office would benefit, not only members of the services, but many outside.—I am, etc.,

Swindon, Feb. 22nd.

A. H. MACLEIN.

#### ROYAL ABERDEEN HOSPITAL FOR SICK CHILDREN.

SIR,—The directors of this hospital have decided to proceed at an early date with the erection of a new hospital. An excellent site has been obtained at Forresterhill, forming part of the ground on which it is hoped to concentrate the hospitals of the city according to the "joint hospital scheme" at present under consideration. Plans have been finally approved for a new children's hospital of 132 beds, with out-patient and other special departments.

While every consideration has been given to economy, it has been found that in order to get a really good and well equipped hospital in which the treatment of the diseases of children can be carried out according to modern standards of efficiency, it will be necessary, at the present high cost of building, to face an expenditure of not less than £110,000. Funds already collected and promised amount approximately to £65,000, and the directors are now issuing an appeal for the remaining £45,000. At a meeting of the honorary staff of the hospital it was resolved that a special appeal be made to all members of the staff, to old residents, and to any graduates of the University of Aberdeen who may care to contribute. We confidently hope that we may be able to collect a sum sufficient for the construction or for the equipment of some special part of the hospital.

The deplorable condition of the present hospital is so well known to graduates, and particularly to old residents, that it is not necessary to enlarge on it here; but it may be emphasized that the age and general unsuitability of the present building hamper, not only the efficient treatment of patients, but the adequate instruction of medical students and nurses. The provision of a new hospital will therefore benefit, not only the community, but also the Medical School in Aberdeen.

I have been asked by my colleagues on the staff to make this appeal through your columns, and we hope that it will meet with a ready response from those to whom it is addressed.

Contributions, marked "Staff Fund," may be sent to Miss Hill, Lady Superintendent of the Hospital, who has kindly promised to acknowledge their receipt.—I am, etc.,

ALEX. MITCHELL,  
Surgeon, Royal Aberdeen Hospital  
for Sick Children.

March 27th.

#### NEED FOR A POST-GRADUATE SCHOOL IN LONDON.

SIR,—Dr. F. Melville Harvey in the JOURNAL of March 28th (p. 637) has struck the right note.

My difficulty has been his—that I cannot be absent day after day. But I, like Dr. Harvey, and no doubt hosts of other men, could arrange one "hospital afternoon" a week practically all the year round, and would gladly pay for a "season ticket"; and, given teachers who can teach, I should consider those four or five hours the best in the week.

But this leads to one other point: Dr. H. B. Newham is reported to have criticized the existing schemes on two grounds. One, that some teachers could not teach; the other, that "curiosities" formed too large a part of the demonstrations. If I may venture to offer suggestions, they would be that on two afternoons in every week there should be four-hour courses—for example, on Tuesday from 3 to 7 p.m. a course at the Brompton Chest Hospital, on Friday at a throat and ear hospital; and each such course

should begin at the very rudiments, and advance through a term of six weeks or so to the requirements of the speciality.

How valuable, for instance, to many of us would be an attendance on four or six consecutive Fridays at a course of instruction on the heart; still more on the lungs.—I am, etc.,

March 30th.

A. O. W.

SIR,—I feel sure many will agree with Dr. Melville Harvey's letter on the need for special post-graduate facilities for London practitioners. It is to be hoped that his proposals will be considered by the Fellowship of Medicine.—I am, etc.,

London, N.W.1, March 30th.

RUSSELL STEELE.

SIR,—It may interest Dr. Melville Harvey to know that there is a post-graduate association in London which might be able to give him what he wants. Any general practitioner in active practice and permanently settled in the London area may become an annual member of the West London Hospital Post-Graduate College at a fee of three guineas a year, and for this he may attend the hospital practice once a week. A syllabus of the work done each day can be obtained on application to the secretary at the College, but as a typical example may I be permitted to set out the Monday afternoon time table.

*In-Patient Work.*—2 o'clock, surgeon No. 1, operations; 2, surgeon No. 2, surgical ward visit; 3, senior physician—medical ward visit.

*Out-Patient Work.*—2 o'clock, medical out-patients; 2, surgical out-patients; 2, diseases of the eye; 2, diseases of women.

On the second Monday of each month, at 4 p.m., a staff consultation is held, when cases of special interest are demonstrated and discussed by members of the hospital staff.—I am, etc.,

March 30th.

HENRY SIMON,  
Dean, West London Hospital.

### ISOLATION HOSPITALS AND SCARLET FEVER.

SIR,—I have no wish to enter into any discussion with Dr. J. A. Milne on his father's method for attempting to prevent the spread of scarlet fever without isolation. My reference was to the Barnardo Homes, Ilford, in which institution the photographs displayed by his father, illustrating the treatment, were taken. At this particular institution the treatment was found to be so inefficacious in the control of scarlet fever that the usual system of isolation is now enforced. Is it not a fact that isolation is now insisted on even at the Barnardo Home, Woodford Bridge, an institution actually under Dr. J. A. Milne's charge? Whether he still employs carbolic oil for its "analgesic" properties is beside the mark. The method was initiated to prevent the spread of infection and avoid the necessity for isolation, and it was on this question that the discussion in the *BRITISH MEDICAL JOURNAL* arose.

There is no need for Dr. J. A. Milne to refer me to the reports of other medical officers of health, with which I am quite familiar. A number of cases are nursed annually in Ilford in their homes (where conditions are suitable), without the Milne treatment, and as a rule there are no return cases. It is altogether a different question whether cases of scarlet fever should be nursed in workmen's dwellings in overcrowded and unhygienic conditions, reliance being placed on the Milne method to prevent the spread of infection.

In the Barnardo Homes, Ilford, taking one year only, the return case rate was 28 per cent. with the Milne treatment; in the same year the return case rate for the Ilford Isolation Hospital without the Milne treatment was 3 per cent. When, however, a full period of isolation was insisted upon at the Barnardo institution the return case rate for both institutions became the same.

These are the facts which Dr. J. A. Milne cannot gainsay. While we all respect his reverence for his father's method I confess I am unable to understand how any medical man could think (in view of our knowledge of

the difficulty of dealing with carriers generally) that the Milne treatment could render the scarlet fever organisms in the naso-pharynx innocuous.

The unchallenged published results, extending over a period of eighteen years, have added the final proof.—I am, etc.,

Ilford, Essex, March 22nd.

A. H. G. BURTON,  
Medical Officer of Health.

### THE TREATMENT OF INFANTILE PARALYSIS.

SIR,—Dr. Charles MacKay (*JOURNAL*, March 28th, p. 634) would give the credit for the muscle re-education treatment to Dr. William MacKenzie in 1915, but I suggest he should go fifty years back and give it to my grandfather, Dr. M. Roth, who, in his book on paralysis in infancy, etc., published in 1869, wrote: "As soon as possible rouse the action of the paralysed muscles by the most important functional stimulus of the will, which cannot be replaced by any other."

In Professor Hey Groves's account of the treatment I was amazed to observe the absence of any mention of the importance of keeping the affected limb warm. I thought it was now generally agreed that the prevention of deformity, the maintenance of warmth, and the re-education of muscles, constituted a trinity, no member of which was efficient without the other two. Did he omit this on purpose?—I am, etc.,

London, W.1, March 28th.

PAUL BERNARD ROTH.

### RADIUM EMANATION (RADON).

SIR,—It has recently been prominently stated in the lay press that the production and clinical use of radon (radium emanation) by the Middlesex Hospital is a "new discovery." In justice to the Radium Institute will you allow me to say that the technique of treatment by radon tubes has been practised here since 1912, and that the method adopted was published in the annual report of this institute for that year? Since that date radon tubes have been supplied in steadily increasing number to medical practitioners and hospitals throughout the country, and 1,067 such tubes were distributed in the year ending December 31st, 1924.—I am, etc.,

The Radium Institute, London, W.1,  
March 30th.

A. E. HAYWARD PINCH,  
Medical Superintendent.

## Medico-Legal.

### AN ALLEGATION OF NEGLIGENCE AT A CONFINEMENT.

GRAY AND WIFE v. PEACOCK.

An action was heard in the King's Bench Division, on March 25th, 26th, and 27th, before the Lord Chief Justice and a special jury, in which William Gray and his wife Alfreda claimed damages against William Ernest Peacock, M.D., a general practitioner of Great Portland Street, London, W., for alleged negligence in treating Mrs. Gray during her confinement. In his reply, Dr. Peacock denied any negligence, and said that if Mrs. Gray sustained any injury it was unavoidable, and that what he did was done in accordance with correct medical practice. The defendant counterclaimed for £42 16s., the amount of his fees. Mr. Barrington-Ward, K.C., with Mr. P. E. Sandlands, appeared for the plaintiffs, and Mr. H. C. Dickens for the defendant.

In opening the case, Mr. Barrington-Ward said that the plaintiffs, now both aged 23, were married in June, 1922. In the following November Mrs. Gray, who had become pregnant, consulted Dr. Peacock, and he undertook to treat her during her confinement for a fee of fifteen guineas. Between January and March, 1923, there were various consultations. It was alleged that at the confinement, on March 26th, the defendant applied forceps in the first stage of labour, and without the plaintiffs' consent. During delivery, shortly before 10 p.m., the perineum was ruptured. Dr. Peacock sent the husband for gut and needles and repaired the tear, but left without removing the placenta, saying that it might come away during the night. At 7 next morning the nurse, who had tried to remove the placenta, telephoned for Dr. Peacock; he arrived an hour later with Mr. R. M. Rowe, and the latter removed the placenta under chloroform. On March 31st the stitches gave way. On May 11th Mrs. Gray consulted Dr. Burnet, who advised her to discharge Dr. Peacock from further

attendance, and six days later she was operated on in a nursing home by Dr. F. J. McCann and Dr. Burnet. Counsel argued that the defendant's negligence had cost the plaintiffs \$220 in fees for the nursing home, nurses, and holidays. The defendant, he said, had not brought to his task that competence and care which the law required of everyone engaged in a skilled profession.

Both the plaintiffs gave evidence in support of counsel's opening speech, and were cross-examined by Mr. Dickens.

Dr. Edward Burnet said that he had had a large obstetrical experience, and expressed the opinion that it would be wrong to use forceps in the first stage of labour. The placenta should never be left unremoved for more than an hour. With a perineum torn as in this case a thorough reparative operation ought to be performed at once after the third stage of labour was concluded. When he first examined Mrs. Gray forty-six days after the birth her condition seemed to him such that she should be attended to without further delay, and he advised her to see a gynaecologist. He came to the conclusion that there was no justification for the damage that had been done or for the delay in repairing it. In cross-examination he said it was about ten years since he last attended a confinement. He did not agree with the school of thought which held that if a first suture failed an interval of three months should pass before re-suturing.

Dr. F. J. McCann, who performed the operation on May 17th, 1923, said that in his view the sooner ruptures of the perineum, such as Mrs. Gray had sustained, were repaired the better. He inclined to the opinion that the operation could properly have been performed before May 11th, when he first examined the patient. It was right to postpone an operation in cases of infection, but when he operated in this case there was no trace of infection. The condition of this patient might, however, quite possibly have been such that it would not have been prudent to perform the operation earlier than it was performed. Assuming that the labour pains began at 8 a.m., and became severe at 8 p.m., it seemed to him extraordinary that forceps should be applied at 9 p.m.; they ought never to be used in the first stage of labour. In reply to the Lord Chief Justice, Dr. McCann expressed the view that the patient's condition was undoubtedly produced by the forceps, but he would not be prepared to say that because forceps had been used such use was improper. Dr. W. E. Falconar also gave evidence for the plaintiffs.

Mr. Dickson, addressing the jury, described it as a monstrous thing to blame Dr. Packard, who was on the spot, and was the best person to judge what should be done. The only charge of negligence against him was that he brought about delivery with undue speed; but that was merely a matter of conjecture, which the medical witnesses for the defence would dispel. The child was born alive and healthy, and who was to say that the defendant was wrong in what he did?

Mr. Aleck W. Bourne, F.R.C.S., said that the injury in this case was one of the commonest happenings in confinements, especially a first confinement. In his view Dr. Peacock acted with fine judgement and skill, and was in no respect negligent. If the mother showed signs of exhaustion or the child showed that it was feeling the stress of labour unduly, it would be quite proper to apply forceps whatever the time.

Mr. Leonard Phillips, F.R.C.S., entirely agreed with what Mr. Bourne had said as to the use of forceps and with his evidence generally. He thought Dr. McCann had been lucky in obtaining a cure after operating so early as May 17th.

Mr. Victor Bonney, F.R.C.S., said he had known defendant for twenty years, and from what he had heard of this case considered Dr. Peacock was justified in the judgment he came to regarding the conduct of Mrs. Gray's confinement. Forceps delivery one hour after the beginning of the second stage of labour was not improper. Rupture of the perineum was not evidence of precipitancy on the part of the attendant; forceps properly applied might minimize the tear. In general, if the first sutures broke down his own practice was to wait six months before attempting operative repair; the reason for this was the risk of septic infection.

Dr. Peacock, giving evidence on his own behalf, said he had been in general practice for thirty years; he had a large midwifery practice, and had never lost a child nor had a case of sepsis. He still considered that he was right in what he did in connexion with Mrs. Gray's confinement. Her exhausted condition, through inability to take food, necessitated the use of forceps. The patient's exhaustion and the risk of sepsis led him to leave the placenta unremoved until the next morning. The first sutures, as often happened, broke down, and he postponed resuturing until such time as he should consider the patient's condition justified it.

Ekonor Ferry, the nurse in attendance at the confinement, described the birth as difficult, and said that before forceps were applied the patient appeared to be suffering from uterine inertia. She heard no complaint about the defendant's treatment of Mrs. Gray while she was attending the case.

Mr. R. M. Rowe, F.R.C.S., who accompanied the defendant to the case on the day after the confinement, said that in his view events justified Dr. Peacock's treatment.

that a doctor, despite his summing up, the Lord Chief Justice said out to practise medicine and surgery he undertook to have a reasonable and competent measure of skill, and to use reasonable care. The jury had to decide whether they were satisfied that defendant used forces in circumstances in which he should not have done so, and if the injury Mrs. Gray afterwards showed was due to the use of forces.

The jury returned a verdict for the defendant, and judgement was entered accordingly for Dr. Peacock on the claim and on the counterclaim for £42 16s., with costs.

### Universities and Colleges.

## UNIVERSITY OF OXFORD.

Radeliffe Prize and Travelling Fellowship.

ON the report of the examiners the Radcliffe Prize has been awarded by the Master and Fellows of University College to John M. H. Campbell, D.M. (Magdalen and New College). The work of Kenneth J. Franklin, M.A., B.M., Fellow of Oriel College, was highly commended. The prize is of the value of £20, and is awarded every two years for research work in medicine by a medical graduate of the University.

The Radcliffe Travelling Fellowship, 1925, has been awarded to Kenneth J. Franklin. The Fellowship is of the annual value of £300, and is tenable for two years, subject to certain conditions of travel and study abroad.

## UNIVERSITY OF DURHAM.

At the convocation held on March 28th the following degrees were conferred: .

M.B., B.S.—J. F. Hedley, Gwendolen Jones, M. H. Jones, W. F. Lascelles,  
H. Levy, F. Lisbman, Charlotte B. Schofield, A. B. W. Smart.

VICTORIA UNIVERSITY OF MANCHESTER.

DR. FREDERICK CRAVEN MOORE, at present lecturer in systematic medicine, has been appointed to the chair of systematic medicine.

## UNIVERSITY OF EDINBURGH.

The Senatus Academicus of the University of Edinburgh proposes to confer at the graduation ceremonial in July the honorary degree of Doctor of Laws upon Dr. A. A. Freeland Barbour, formerly Lecturer in Gynaecology, University of Edinburgh, Mr. Alexander Miles, M.D., F.R.C.S.E., formerly Lecturer in Clinical Surgery, University of Edinburgh, Dr. Robert Muir, F.R.S., Professor of Pathology, University of Glasgow, and Sir Harold J. Stiles, K.B.E., Regius Professor Emeritus of Clinical Surgery, University of Edinburgh. On the occasion of the meeting in June of the Interstate Post-Graduate Assembly the honorary degree of LL.D. will be conferred upon Dr. Charles H. Mayo, of Rochester, Minnesota.

At a graduation ceremony, held on March 26th, the following degree and diploma were conferred:

D.Sc. (Department of Pure Science).—Eric Ponder, M.B., Ch.B.  
D.P.H.—W. N. J. Chapman.

## UNIVERSITY OF ABERDEEN.

THE following candidates have been approved at the examinations indicated:

M.D.—M. M. Cruickshank, A. Mitchell, R. R. Trull, J. Maclellan.  
 FINAL M.B., CH.B.—P. Baser, H. C. Denney, W. Booth, L. Chanock.  
 \*A. Cruickshank, R. A. Jamming, J. M. Davidson, G. M. Davis.  
 C. A. Deane, J. Cessi, R. A. Dingwall, \*C. S. D. Don, A. T. Duncan.  
 C. A. Public, Margaret M. Gair, A. Galloway, J. A. Gordon.  
 J. P. Gordon, T. B. Gordon, Janet Johnston, W. Kelly, D. B. Laine,  
 J. Macarthur, \*P. D. A. Macdonald, K. C. Mackenzie, D. M. Mac-  
 kinnon, F. S. McLean, Anno G. I. Maclellan, \*W. A. Mac,  
 G. W. Mearns, L. Morgan, J. A. Mulligan, N. M. Munro, \*J. A. R.  
 Paterson, O. G. Prosser, W. J. Raiff, \*  
 son, \*M. C. G. Robertson, A. A. Simpson  
 Barbara W. Spark, D. S. Stewart, J.  
 J. D. Walker, \*R. W. H. Welch, A. D. F. White, A. R. Wilson.  
 Charlotte M. Wilson, D. E. Wilson.

\* Passed with distinction.

## UNIVERSITY OF DUBLIN.

SCHOOL OF PHYSIC, TRINITY COLLEGE.

THE following candidates have been approved at the examination indicated:

FINAL M.B., PART I.—*Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene*.  
 O'Meara, J. W. Bowden, A. O.  
 Keown, J. H. McLean, J. B.  
 Brooks, J. N. S. Gonyea, J. W.  
 D. St. C. Mackenzie, G. C. Hardy,  
 D. J. Roux, J. Johnston, Christina M'Donald, Rachael E. Porter, Craig,  
 J. Quigley.  
 PART II.—*Medicine*. \*T. W. MacDowell, C. F. D. McCallin,  
 W. C. Somerville La ge, Kathleen P. Morrison, G. F. Gillespie,  
 E. M'Alpine, W. H. Anderson O'D. T. D. Browne, J. R. Gregory,  
 R. T. Cronin, J. Dick, T. C. Foster, P. N. H. Labuschagne, W. B.  
 Roastree, F. M. Purcell, N. M. Greaves, F. J. Marais, Annie T.  
 Deane, F. H. McKenna, J. V. Morris R. W. Harte, J. Cusseo, G. P.  
 Bamford, O. Chance, W. P. E. M'Intyre, Augusta M. Young,  
 W. Gallagher, J. L. Leviington, J. L. Marshall, Mary Galvin, F. V.  
 Duke, G. Lord-Flo-  
 H. Nelson, E. J. Horwich,  
 W. A. Redmond, B. J. Carson,  
 E. T. C. S. Rudd, E. f. L. C. Brough,  
 H. W. Strong, J. M. Johnston, C. du Plessis, E. J. Walsh, J. E. Beatty, J. Crawford, F. J. Marais, L. M. Whitsitt, E. A. Bennett, R. J. G. Hyde, J. G. Maguire, G. W. Garde, W. C. G. Potts, C. R. Moore, H. Brney, R. V. Franklin, R. A. Heatley, I. Sirasburg, Midwifery: \*C. R. Bo'and, \*J. F. Wildo, \*R. L. Forsyth, \*E. Rakoff, Elsiebeth V. D. Hewat, F. H. McKenna, J. E. Stokes, G. D. Edwards, A. A. Shañik, M. Shorov, W. Pike, L. W. R. Ha' Galvin, Henrietta Arms  
 M.Ch.—D. de Bruijn  
 M.A.O.—D. J. Malan.  
 DIPLOMA IN GYNAECOLOGY AND OBSTETRICS—Elizabeth M. Thompson

\* Passed on high marks.

LONDON SCHOOL OF HYGIENE AND TROPICAL  
MEDICINE.

## DIVISION OF TROPICAL MEDICINE AND HYGIENE.

THE following medical officers passed the school examination at the termination of the seventy-seventh session (January-March, 1925):

\*A. C. Craighead (Duncan medal), \*A. N. Haworth, \*R. Klaher, \*N. E. Goldsworthy, \*A. S. Mohamed, K. Lumsden, W. J. Vickers, P. C. C. Garnham, A. H. Campbell, E. N. Cook, J. N. Banks, J. W. Graham, A. H. Monks, R. M. Fraser, L. B. Struthers, P. F. A. Giot, H. H. Brown, J. H. Bowyer, M. Ali, J. Gordon, J. Manley, R. C. Spiers, T. S. Goodwin, F. G. Read, M. Lal, H. J. More, J. Enzer, O. G. Wilde, R. W. C. Thambiah, A. N. Coomarasamy, G. M. Moffatt, A. H. Macleod, J. L. Stuart, R. H. Mumford, T. C. Pan, V. F. T. Chan.

\* With distinction.

## The Services.

## FOREIGN DECORATIONS.

THE following are among the decorations and medals awarded by the Allied Powers to British forces for distinguished service rendered during the war 1914-19.

BY THE PRESIDENT OF THE FRENCH REPUBLIC.

*Médaille de la Reconnaissance Française*.—Eo Argent: Captain W. K. Campbell, D.S.O., M.B.E., M.C., R.A.M.C.; En Bronze, Major Wilfred Vickers, D.S.O., Army Medical Corps, Australian Imperial Force.

BY THE KING OF THE SERBS, CROATS, AND SLOVENES.

*Gold Medal for Distinguished Service*.—Captain W. L. Murphy, R.A.M.C.(T.F.).

*Silver Medal for Distinguished Service*.—Captains G. S. Davidson and E. D. D. Dickson, R.A.M.C. (S.R.).

## DEATHS IN THE SERVICES.

Lieutenant-Colonel David Wilson Scotland, Bengal Medical Service (ret.), died at Colinton, Midlothian, on February 19th. He was born at Saharanpur on November 16th, 1861, and was educated at Edinburgh, where he graduated M.B. and C.M. in 1886, and M.D. in 1899. He entered the I.M.S. as surgeon in 1886, became lieutenant-colonel after twenty years' service, and retired in 1907. Most of his service was spent in civil employ in the North-West Provinces, now the United Provinces of Agra and Oudh. He received the order of the Kaisari-Hind, second class, 1900.

Lieut.-Colonel John Gover Williamson, R.A.M.C.(ret.), died at Hastings on January 18th, aged 76. He was educated at St. Bartholomew's Hospital, and took the diplomas of M.R.C.S. and L.S.A. in 1869, and of L.R.C.P.Lond. in 1870. He entered the R.A.M.C. as assistant surgeon in 1871, and during his early years he served in the 65th Foot, now the 1st battalion of the York and Lancaster regiment. He attained the rank of brigade surgeon lieutenant-colonel in 1895, and retired in 1896. After retirement he was employed at Bull Point from 1896 to 1905, and at Leicester from 1905 to 1913. He served in the Afghan war of 1878-80, receiving the medal.

Lieut.-Colonel John Robert Stuart, R.A.M.C.(ret.), who died at Allassio, Italy, on February 27th, was born at Inverness on March 18th, 1855, the son of the late Colonel J. R. Stuart, Royal Scots Fusiliers. He entered the army as surgeon on February 3rd, 1883, became lieutenant-colonel after twenty years' service, and retired in 1910. He served in the Nile campaign of 1898, when he was present at the battle of Omdurman, and received the medal with a clasp and the Egyptian medal.

## Obituary.

DR. JAMES TAYLOR of Clifton, Bristol, who died on March 22nd, aged 71 years, was the elder of two sons of the late Dr. James Taylor, who practised at Bristol. He was educated at Bristol and Edinburgh, and took the diplomas of L.S.A. in 1875 and M.R.C.S.Eng. in 1876. He was one of the early workers in radiology, being the first skiagraphist appointed to the Bristol Royal Infirmary; on his retirement from that post he was appointed consulting radiologist to the infirmary. He held a commission as captain R.A.M.C.(T.), and was attached to the 2nd Southern General Hospital. Dr. Taylor was an enthusiastic musician, and often assisted the Medical Dramatic Club and the old Clifton Amateur Operatic Society in their performances. He was a member of the Bristol Division of the British Medical Association and of the Bristol Medico-Chirurgical Society.

Dr. NOGUEVUS, professor of children's diseases in the University of Valladolid, has recently died of leukaemia, at the age of 40.

Professor F. VILLAR, a well known surgeon of Bordeaux, has recently died.

## Medical News.

OWING to the Easter holidays it will be necessary for the next issue of the BRITISH MEDICAL JOURNAL to go to press a day earlier than usual. All communications and advertisements intended for insertion in the issue dated April 11th must therefore be received not later than Monday, April 6th. The offices of the British Medical Association and JOURNAL will be closed from Thursday evening, April 9th, till Tuesday morning, April 14th. We regret that, owing to a dispute between the Federation of Master Printers and the National Union of Printing, Bookbinding, Machine Ruling, and Paper Workers, there was some delay in issuing and dispatching the JOURNAL for last week, but no time was lost so soon as the dispute was settled.

THE Fellowship of Medicine announces that Sir Arbuthnot Lano will preside at the resumed discussion on post-graduate study in London at the house of the Royal Society of Medicine on April 8th, at 6 p.m. It is hoped that many members of the medical profession will attend and express their views. During the fortnight commencing April 20th there will be an intensive course in medicine, surgery, and the specialties at the Hampstead General Hospital, a course in diseases of children at the Queen's Hospital, Hackney Road, E.2, and a course in proctology at St. Mark's Hospital. Copies of the syllabus of these courses may be obtained from the Secretary to the Fellowship of Medicine, No. 1, Wimpole Street, W.1.

UNDER the auspices of the Strasbourg Faculty of Medicine an intensive post-graduate course in tuberculosis has been organized by Dr. Vaucher, general secretary of the Anti-tuberculosis Association of Alsace-Lorraine. It will be held in Strasbourg from October 9th to 24th, and will include lectures by a number of teachers in the faculty on various aspects of medical and surgical tuberculosis; instruction will be given also in bacteriology, radiology, and the operation of artificial pneumothorax. The fee for the course is 200 francs; further information may be obtained from Dr. Vaucher, 22, rue de l'Université, Strasbourg.

THE Physiological Society is meeting this week-end in Holland. The main business will be conducted in the Pharmacotherapeutical Institute and physiological laboratory at Leyden. A visit will also be paid to the physiological laboratories at Utrecht.

THE course in parasitology to be held in the Tropical Division of the London School of Hygiene and Tropical Medicine from April to June will commence on April 27th, and not as previously printed. Inquiries should be addressed to the Director of the School, c/o Institute of Historical Research, Malet Street, W.C.1.

THE Royal Microscopical Society will hold a conference in the University of Sheffield on April 20th, 21st, and 22nd. The first paper will be read by Mr. J. E. Barnard, F.R.S., of the National Institute of Medical Research, who will deal with modern microscopical methods. Papers having a pathological bearing will be read by Dr. W. E. Cooke on pernicious anaemia, by Sir Kenneth Goadby on lung fibrosis in iron mining, and demonstrations of the Golgi apparatus will be given by Dr. C. Da Fano, Mr. A. Subba Rao, and Dr. F. W. R. Brambell. A paper on the cytology of cancer will be read by Dr. R. J. Ludford. There will be a trade exhibition of scientific instruments and apparatus, and visits will be paid to several of the chief steel works in Sheffield.

THE Dutch Congress of Natural Science and Medicine will be held at Groningen from April 14th to 16th, when the following papers, among others, will be read in the Medical Section: psychological manifestations and x-ray diagnosis in cerebral tumour, by Professor C. Winkler of Utrecht; surgical treatment of cerebral tumour, by Professor H. J. Lameris of Utrecht; the study of intestinal motility, by Dr. B. Lauwers of Conrath; aneurysm of the aorta, by Dr. A. de Groodt of Antwerp; operative treatment of the small prostate, by Dr. G. van Houtum of the Hague; gastric syphilis, by Dr. J. Koopman of the Hague; the question of diabetes, by Professor Hijmans van den Bergh of Utrecht; active immunization against diphtheria, by Professor H. Aldehoff of Utrecht; and the question of constitution in gynaecology and obstetrics, by Dr. R. Remmelts of Amsterdam.

THE next election to the Grocers' Company's research scholarships, founded to encourage original research in sanitary science, will take place in May next. They are each of the value of £300 a year, with an allowance to meet the cost of apparatus and other expenses, and are renewable for a second or third year. Forms of application and further particulars can be obtained from the Clerk of the Grocers' Company, Grocers' Hall, London, E.C.2.

## An Address ON OCCUPATIONAL AND OTHER CAUSES OF PULMONARY FIBROSIS.

DELIVERED TO THE NORTH OF ENGLAND BRANCH OF THE  
BRITISH MEDICAL ASSOCIATION, FEBRUARY 19th, 1925,

BY

SIR THOMAS OLIVER, M.D., F.R.C.P.,  
PROFESSOR OF MEDICINE, UNIVERSITY OF DURHAM AND COLLEGE OF  
MEDICINE, NEWCASTLE-UPON-TYNE.

Four years ago I gave to this Branch a demonstration of the pathological changes met with in fibrosis of the lungs caused by inhalation of dust by men following certain occupations, such as that of ganister mining and crushing, also by gold-miners who had worked in the Transvaal. I now wish to extend my remarks by drawing attention to other forms of illness during or after which, if the patient survives long enough, structural changes occur in the lungs, whereby they lose their spongy character, and, instead of remaining air-filled and elastic organs, they become semi-solid and unable to retract.

In order to appreciate what is meant by pulmonary fibrosis it is well to visualize a type of lung consolidated by an excessive increase of fibrous tissue, such as the lung of a gold-miner who has died of the malady. It was during and shortly after the close of the South African war that men who had previously been coal-miners in the Northumberland pits, and who had gone seven or eight years previously to South Africa, attracted thither by the high wages, were returning home with well lined purses, but, alas! only too frequently to die within a year or two of silicosis, caused by inhalation of dust given off during drilling of the rock in the mines of the Transvaal. As I was consulted by many of these men, they supplied me with the experience which formed the basis of my paper, entitled "Gold-miner's phthisis," published in the *Lancet* in 1902. Some of the men looked rather bronzed and weather-beaten, but the one particular circumstance which caught my attention was the marked dyspnoea which even the slightest exertion induced. On getting up from one chair in my consulting room to move to another, or on taking a few paces in the room, the breathing became short and difficult, so that the patients were glad to sit down and rest. I was impressed, too, by the marked reduction of their respiratory capacity. In many of the men, instead of there being a difference in chest measurement of two to three inches between inspiration and expiration, it was frequently only one inch. Here and there in the chest small areas of dullness were appreciable, especially towards the bases. The respiration was deficient in places, while over other portions of the lungs there could be heard small bronchial râles; but whether râles were heard or not the dyspnoea was always in excess of the physical signs.

If it was a miner whom I was examining in the early stages of the illness, few physical signs might be detected; probably the patient had lost weight, and was the subject of cough as well as of shortness of breath. In the early stages expectoration was not abundant, and on microscopic examination it was found to be free from the presence of tubercle bacilli. In some instances the illness pursued its course to a fatal termination without the lungs becoming tuberculous, as confirmed by *post-mortem* examination. The lungs would be found greyish-black in colour, hard to the touch, stony hard in fact, and giving rise to a gritty sensation on being cut with the knife. In the lungs of many of the men there were no signs of cavity, large or small, so that silicosis in its inception, and all through its duration, can be, and frequently is, a non-tuberculous disease. Some of the patients subsequently became tuberculous, and this was indicated by a rise of the evening temperature, by sweating, increase of cough, and expectoration in which tubercle bacilli might be found. When the malady had progressed to a further stage, the breathing would be found to have become still shorter; occasionally haemoptysis occurred, or the expectoration would be slightly streaked with blood; the expansion of the chest tended to become

more restricted, owing to extension of adhesions between the bases of the lungs and the diaphragm; dullness on percussion increased in area; moist râles became more abundant, and as digestion became impaired the general health declined correspondingly. On x-ray examination of the chest mottling of the lung in places could be detected.

It is interesting to compare the lungs of coal-miners with those of men who have followed such dusty occupations as ganister mining and crushing, also gold-mining. Ganister is a siliceous clay which is made into bricks for lining iron and steel furnaces, since the bricks are capable of withstanding enormously high temperatures. Of the various kinds of dust inhaled by workmen, that which contains silica is one of the most dangerous. Formerly it was taught that the injury inflicted upon the lung and which ended in fibrosis was the result of the physical action of the particles of dust. Since many of these are sharp-pointed, it was believed that during inhalation these were carried beyond the protective barrier of ciliated epithelium, much of which had probably disappeared as the result of recurrent catarrh, and having reached the small bronchi and the pulmonary alveoli they inflicted damage of a purely physical character. This is no longer regarded as the complete explanation. Professor Haldane of Oxford and Mavrogordato have shown by their experiments that when fine particles of soft coal are inhaled these are met by a reactive resistance on the part of the bronchial mucous membrane and the pulmonary alveoli, during which the large wandering cells lying in the alveoli, or on the inner surface of the minute bronchioles, take up the carbon particles, and as these cells are phagocytic in their function and are subsequently passed up into the bronchi, many of the carbon particles which have been inhaled are in this manner eliminated. Silica dust, on the other hand, is not readily soluble, nor are its particles easily phagocytosed; they penetrate into the lymphatics of the lungs and are carried to the glands at the hilum, or they induce pulmonary fibrosis. Although silica dust is very insoluble, yet Gye and Kettle have demonstrated that silica may become soluble in the lungs, and that the dissolved material is equally capable of acting harmfully upon the pulmonary tissue. The injury thus inflicted upon the lungs would be, according to this theory, not the result of the physical but of the chemical properties of the dust.

There still remains, however, the probability that the inert or undissolved particles of silica also play a considerable part in inducing inflammatory reactions in the lungs, and this raises the question as to how far the size of the particles can be regarded as contributing to the subsequent structural changes. On examining microscopically a section of a silicotic lung, the fibrotic portions appear as if they had been peppered with very fine dust. By means of a micrometer the size of these particles can be estimated: they are measured to one-thousandth part of a millimetre, the unit being known as a micron ( $\mu$ ). Pathological research in this country has shown that the larger number of particles present in the lungs are below 1 micron, and seldom above 2, although they may sometimes measure 10 microns or more. It would therefore appear as if it was the particles below 2 microns which are the most dangerous, so that while a man may be working in a thick atmosphere heavily laden with dust, readily visible to the naked eye, yet if most of these particles are above, say, 50 microns, there is less likelihood of this dust causing silicosis than an atmosphere in which the particles are smaller than 2 microns in dimension. It is these which, when inhaled, overleap the protective epithelial barrier in the larger respiratory passages and reach the lungs.

During the time I was following up the subject of Rand miner's phthisis from the clinical point of view, it was my wish to become practically acquainted with, as nearly as possible, the conditions under which gold-miners had been working. Accordingly I visited the tin mines in Cornwall, where rock drilling was much in use. The Cornish mines are much deeper than the coal-mines in the North of England, and the rock is harder. Along with an under mine manager, a working miner, who was an experienced rock driller, and the doctor, I went into a mine wherein we crawled through an opening into a chamber from which a certain amount of ore had already been extracted. After

we had squatted as best we could the rock drilling was begun. In a few minutes the atmosphere became so thick that breathing was, to those of the party unaccustomed to dust, somewhat uncomfortable and difficult, and although we were all squatting closely together we could not see each other. Even the glare of our lights could not penetrate the dusty atmosphere. In addition, as no air was circulating through the chamber, the temperature became uncomfortably hot. Subsequently we removed ourselves, as best we could, from the confined space, and travelled into one of the main ways where the air was clear and cool. We inspected other sections of the mine, and in two hours returned to the place where we had witnessed the rock drilling. By this time the dust had considerably settled and the air had become comparatively clear.

We were now to have the opportunity of seeing automatic water spraying carried on simultaneously with the rock drilling. The difference between the two operations was remarkable. Instead of the atmosphere becoming thick and dusty, and the temperature raised, the air remained clear, the temperature low, and we could not only see each other quite well, but could converse without difficulty. As to the utility and efficacy of water spraying during rock drilling there can be no doubt; but while water spraying lays dust, many of the finest particles may yet rise into the atmosphere with the spray, and although these particles may not be visible, yet it is they which, when inhaled, harmfully affect the lungs.

One of the dustiest industrial operations I have seen is asbestos crushing, carding, and grinding. Some of you have probably not seen asbestos in its native condition. It is an extremely hard rock with small white fluffy fibres attached to it, almost like finely frayed cotton wadding, and therefore suggesting vegetable origin, but it is really a mineral substance. The rock is crushed in closed machinery, but much fine dust and fibre escape into the workroom. From the finely comminuted pieces of stone the fibre is separated by a mechanical process of teasing, so that the material as it passes away from the machine looks like raw cotton, only the fibres are loose and not so adhesive. During these processes the atmosphere of the workroom is quite cloudy; the hair and clothing of the men become covered with white fluff. Even by brushing I had difficulty in removing the material from my clothes. After having been teased, the material is passed through carding machines, so as to transform it into a cord-like structure; this is subsequently spun or is woven into the flat plaques of asbestos with which all of you are familiar. I was rather surprised when the manager of the works informed me that the men never suffered from respiratory troubles. That such existed I had not the slightest doubt. In the *BRITISH MEDICAL JOURNAL* of July 26th, 1924, this was definitely shown by Dr. W. E. Cooke of Wigan in an interesting article entitled "Fibrosis of the lungs due to the inhalation of asbestos dust." So far as I know this is the first paper on the subject in the English language. Dr. Cooke informs us that asbestos contains, amongst other compounds, calcium and magnesium silicate, and 40 per cent. of  $\text{SiO}_2$  or silica. The mineral fibre is translucent, except at the fractured ends, where it is blackened. The patient whose illness and death supplied the basis of Dr. Cooke's information was a woman, aged 33, who had worked in asbestos factories since the age of 13—that is, for twenty years. Between 1917 and she had remained away from the factory, but subsequently she worked at intervals, and died in March, 1924. X-ray plate showed extensive fibrosis with calcareous nodules at the root of the lungs. On section the right lung was found to be fibrosed and airless; there was a large cavity in the apex and the pleura was thickened. The left lung was adherent and its pleura in places was also thickened; this lung too was considerably fibrosed. On microscopical examination fibrotic changes were very marked; around the caseating areas in the lungs giant cells and tubercle bacilli were found. The case was therefore one of silicosis accompanied by tuberculosis, the tubercle having been a later development, for Professor J. M. Beattie of Liverpool, whose research work on dust and pneumoconiosis is well known, has experimentally produced fibrosis in animals by causing them to inhale asbestos dust.

While mineral dust is a frequent cause of pulmonary fibrosis, the structure of the lung can be similarly altered by micro-organisms or their toxins in such diseases as tubercle and syphilis. Upon some of the less well known associations of these I should like to say a few words. In silicosis the pathological changes occur around the minute bronchi and within the alveolar septa. A little while ago my attention was drawn by Professor Stuart Macdonald to fibroplastic changes which had taken place in the lungs of one of my patients who had died from croupous pneumonia, but therein, and differing therefore from what occurs in silicosis, the initial changes had commenced within the exudate in the alveoli, and were rapidly leading to organization. In some of the alveolar spaces wherein the exudation had become softened, and partly removed by absorption, the leucocytes which had continued to be healthy and active were becoming transformed into fibroblasts, and these, becoming superimposed, lined the interior of the alveoli, and were gradually obliterating them. Had my patient lived long enough there would probably have occurred real fibrosis of those portions of the lung which had been during life the site of croupous pneumonia. This, I admit, is rather an uncommon sequel of pneumonia, for the exudate is usually absorbed, and the lung regains its previous resiliency.

In syphilis a similar thickening takes place; there may be gummata or diffused interstitial fibrosis. In the diffused form there is hyperplasia of the connective tissue. The alveolar walls become thickened, dense masses of fibrous tissue are formed in which the remains of compressed alveoli can be detected, and the walls of small blood vessels are thickened.

#### *Influenza and Pulmonary Fibrosis.*

A year ago Dr. Bernard Shaw gave an interesting demonstration, illustrated by lantern slides, of the relationship between influenza and pulmonary fibrosis. After showing how rapidly the epithelial lining of the small bronchi and the alveolar walls become destroyed in influenza, he indicated that just as rapidly were reparative processes taking place with, as a result, occlusion of several of the minute bronchi; the alveolar walls, too, were thickened by organization of fibroblasts; newly formed capillaries also could be observed extending into the leucocytic exudate whereby this material became changed into granulation-like tissue. There thus occurs early in some forms of influenza a rapid tendency to the development of pulmonary fibrosis.

In almost a similar manner the bronchopneumonia which accompanies measles is followed by an increase of the interstitial tissue of the lungs. This is the case in children, and is frequently the explanation of the lung troubles from which they suffer in later years. During the recent war similar changes were observed in the lungs of several of the United States soldiers who had been drawn from the agricultural areas. These healthy men when housed in barracks and overcrowded buildings, during their military training, became an easy prey to measles. Many of the men succumbed to the accompanying bronchopneumonia, and in their lungs fibrotic changes were found to have already taken place.

There is a growing opinion that a silicotic lung is more liable to become affected by tubercle than a non-silicotic. It would almost appear as if a larger percentage of gold-miners affected by silicosis had during recent years become more liable to pulmonary tuberculosis than three decades ago. It may be that the men had been brought into more immediate contact with infection than previously. In a well marked case of dust disease of the lungs the fibrous tissue is hard and thick, and it hardly seems to offer favourable conditions for the reception and multiplication of tubercle bacilli. But while certain portions of lung are fibrosed other portions are the seat of bronchial catarrh, so that it is possibly in those portions of the lung that the tubercle bacillus finds a suitable nidus for its development.

The causes of pulmonary fibrosis with which we have been concerned have in the main operated from within the alveoli inwards—that is, towards their interstitia. Frequently the operative agent has been inhaled dust,

or, it has been the presence of toxins in the exudate acting upon leucocytes therein and converting them into fibroblasts.

In my visit to Harvard University a little over a year ago I was extremely interested to learn from Dr. Drinker of some experiments he had been carrying out in regard to pulmonary fibrosis. It had occurred to Drinker that since fibrotic changes in the lungs are the result of inhaled dust having penetrated the alveolar wall and induced irritation of the interstitial tissue, possibly a similar chain of events might take place if particles of insoluble dust were injected into veins not far distant from the heart. Accordingly Drinker injected into the veins of animals extremely minute particles of manganese silicate, and he found that structural alterations were established in the lungs. Since my conversation with Dr. Drinker I have carried out a series of experiments on the Harvard lines, but instead of using manganese silicate I employed finely powdered bauxite, an aluminium ore. This was conveyed into the auricular veins of rabbits, and after a series of injections conducted over a few months we found in the microscopical sections of the lungs, kindly prepared for me by Mr. John Secker of the Physiology Department, large phagocytic cells lying within the alveoli and laden with dust particles, similar cells surrounded by mucus passing outwards by the small bronchi, and the same type of cell in the spleen. Until the series of experiments which I am at present carrying out is concluded, it is somewhat difficult to explain the presence and escape of the phagocytic cells alluded to. They are not leucocytes in the ordinary acceptance of the term. When an injection of finely divided particulate material is made into the veins of an animal not far from the heart the particles are carried along in the blood stream, and as the pulmonary capillaries are those through which, after leaving the heart, they would primarily pass, several of the particles are probably taken up by the endothelial cells. From the size and shape of the phagocytes found in the pulmonary interstitia and alveoli, also in the minute bronchi, the probability is that they are endothelial cells which have broken off from the pulmonary capillaries, and that they were fulfilling their function of eliminating foreign material from the blood. Their presence in the splenic pulp is similarly explained.

## PROLONGED MENINGOCOCCAEMIA WITH TERMINAL MENINGITIS.

BY

G. LOVELL GULLAND, C.M.G., M.D.,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH;  
PROFESSOR OF MEDICINE AND CLINICAL MEDICINE IN THE  
UNIVERSITY OF EDINBURGH;

AND

W. R. LOGAN, M.D., F.R.C.P.E.,

CLINICAL PATHOLOGIST TO THE ROYAL INFIRMARY, EDINBURGH.

THE following record emphasizes the importance of searching for the meningococcus in obscure cases of pyrexia, particularly of an intermittent type.

The patient was a man of 57, an engine fitter, who had been unusually healthy. For thirty-four years he had not lost a day's work; he lived comfortably, and was a teetotaler. About the beginning of May, 1924, he had an attack of so-called "influenza." It commenced abruptly with shivering and fever, but he had no headache or other pain, and no catarrh or pulmonary symptoms of any kind. He had some vomiting, and in a day or two slight diarrhoea came on, which lasted only a few days. Weakness was really the principal symptom. The fever was not continuous, but he had rigors at odd times, apparently almost daily. He was in bed for eight or nine weeks. He was up for about a fortnight before he was admitted to Ward 32, but could hardly walk because of weakness, and he had lost nearly 3 st. in weight. He came into the infirmary on July 8th, 1924.

His only symptoms were weakness and loss of appetite; the appetite returned after a few days in hospital. Physical examination gave entirely negative results, and need not be detailed. All the systems were normal for a man of his age, and remained so throughout. The spleen was not enlarged at any time. For the first two days the temperature remained

normal; on the third day it went up with a slight rigor, but only to 100° F., the next day to 101°, and on that day his white count was found to be 10,400. Throughout the illness this leucocytosis with polymorph increase persisted; the highest figure reached was 29,100, a month later.

From this time onwards there was, in the way of symptoms, nothing but increasing weakness. The temperature followed a most erratic course; on some days, and sometimes for two or three days together, there would be only a slight rise, say to 100° F., on others, coming singly or in small groups, rigors, when the temperature ran up for a short time to, say, 103°. These occurred at any hour of the day or night; between times the temperature was generally subnormal. From August 26th to September 9th the rigors occurred daily, and were more severe; the temperature was higher, reaching 104° or over on most days. The pulse rate varied strictly with the temperature: when it was subnormal the pulse was in the 60's, when it reached 104° it often ran up over 120. In the same way the respiration rate varied from 20 to 32.

Throughout this period everything we could think of was investigated in the hope of getting some light. The chest was x-rayed, with negative results; the urine was examined daily and was always normal. Though the persistent leucocytosis made enteric or malaria unlikely, the blood was subjected to the Widal test for the usual organisms, with negative results, and examined constantly for plasmodia, equally unsuccessfully. The spirochaete of rat-bite fever was sought in vain; the patient denied ever having been bitten by any animal, and it was only about ten days before his death that his wife remembered that about the middle of April he had been badly scratched on the back of the hand by a "wild" cat that lived by rat-catching. This led to several intravenous injections of novarsenobillon, without improvement. The Wassermann test was negative in both blood and cerebro-spinal fluid, and the latter showed no increase of cells and no organisms on culture. The first blood culture, in July, gave a growth of staphylococci and Gram-negative diplococci. As the staphylococci were almost certainly a contamination, it was thought the diplococci might be so also; but the observation was repeated a few days later and they were found alone, and again on August 12th. A blood culture was not made again till September 8th, and then no organism of any kind was found. Cultures were taken from the urethra, but no diplococci were found.

About September 9th meningeal symptoms began to develop—headache, head retraction, drowsiness, and incontinence of urine and faeces. The temperature was more continuously raised, seldom dropping to normal, but never running above 101°; usually it was about 100°. The rigors ceased. The patient gradually became weaker, emaciated very rapidly, grew more drowsy, and died suddenly on September 16th.

The first lumbar puncture to yield positive results was made on September 11th. The fluid was definitely under pressure, was turbid, and microscopically showed many polymorphs and large lymphocytes. In some parts of the films diplococci were found, practically all intracellular, and always in the large lymphocytes, never in the polymorphs. The same diplococcus which had been found in the blood was grown from this fluid. As lumbar puncture gave relief it was repeated daily. On the 12th the cell count was 5,800 per cubic millimetre. In the later punctures the fluid became clearer.

*Post mortem* a certain amount of bronchitis and hypostatic congestion of lungs were found. The heart was practically normal; very slight atheroma in the aorta; liver normal, except for some cloudy swelling and perhaps fatty degeneration; spleen not enlarged, apparently normal; cortex and medulla of both kidneys slightly narrowed; other organs all normal except the brain. The pia arachnoid showed areas of localized thickening in various parts, chiefly towards the base and over the cerebellum. These were evidently patches of meningitis, and on section microscopic examination confirmed this view. There was a marked exudate, with numerous polymorphs; slight excess of cerebro-spinal fluid, with slight dilatation of the ventricles internally, but the brain substance was normal.

Cultures made *post mortem* from the heart blood, spleen, and liver remained sterile, but the organism was obtained from the exudate at the base of the brain.

### The Micro-organism.

The diplococcus, when first obtained from the blood stream, resembled a meningococcus in its cultural characters, save that it grew more readily on ordinary media than do most strains of meningococcus. On plain agar slopes it grew well, even when inoculation was not particularly heavy, and when no accessory substances could have been carried over from the original medium. Growth on glucose-ascetic fluid agar (Thomson's) was profuse. After subculture for some time it lost this readiness of growth to some extent, and finally became indistinguishable culturally from type strains of meningococci, so far as readiness of growth on various media was

guishable from the meningococcus; it produced acid in glucose and maltose, no change in lactose, saccharose, and salicin. The gonococcus does not ferment maltose,

while *Micrococcus catarrhalis* ferments neither maltose nor glucose.

A rabbit and guinea-pig inoculated with cerebro-spinal fluid containing the organism showed no effect, though the guinea-pig died about a fortnight later. No pathological lesions were discovered, and cultures made from its brain and organs did not yield the organism in question.

Guinea-pigs inoculated with the patient's whole blood, with the plasma, and with cultures of the organism yielded similar negative results.

No agglutinating serums for meningococci could be obtained from various sources tried. A commercial polyvalent antimeningococcal serum did not agglutinate the organism even in low dilutions, but as it did not agglutinate the type strains of meningococcus I, II, III, and IV either, this observation was obviously not of value.

A beginning was therefore made in the immunization of two rabbits with the diplococcus from the patient. The organism was first found in the patient's cerebro-spinal fluid on September 11th. It was present in films of the fluid only in small numbers, but growth was obtained, although with difficulty. As obtained from the spinal fluid, it did not grow nearly so profusely as it had when obtained from the blood stream. It behaved now, in short, as a meningococcus, and there was now no hesitation in labelling it as such. The patient died before the agglutinating serum from the rabbits was ready.

Four type strains of meningococcus (Lister Institute Collection) were tested with the serum along with the organism under examination (the "Murray coccus"). The emulsions were made in saline from growths on Thomson's medium, and the macroscopic method in a water-bath at 55° C. was used. Readings were made at intervals up to four hours. Both serum and saline controls were used. The test was not carried beyond 1 in 64 with Type III meningococcus.

Identification of Type of Meningococcus.

	Murray coccus serum: Dilutions, one in—									Controls.
	16	32	64	128	256	512	1,024	2,048	4,096	
Murray diplo- coccus	+++	+++	+++	++	++	++	+	+	Trace	—
Meningococcus Type I	±	Trace	—	—	—	—	—	—	—	—
Meningococcus Type II	+++	+++	++	++	+	±	±	Trace	—	—
Meningococcus Type III	++	±	Trace	—	—	—	—	—	—	—
Meningococcus Type IV	++	±	±	Trace	—	—	—	—	—	—

+++ represents complete clearing with sedimentation, and the other signs correspondingly smaller degrees of agglutination.

The organism could therefore be definitely labelled meningococcus Type II of Gordon's types.

Dock<sup>1</sup> has recently analysed sixty-eight reported cases of meningococcaemia, occurring in different parts of the world. In the case which he studied personally the organism was not agglutinated by the patient's serum or by polyvalent antimeningococcus serum at the second or third subculture, but at a later date was agglutinable in low dilutions both by antimeningococcus and antigenococcus serums. It was at first thought to be a gonococcus, but ultimately determined to be a meningococcus. The intermittent character of the fever, often with a definite malaria-like periodicity, was a salient feature of these cases.

Rolleston<sup>2</sup> also drew attention in his Lumsian Lectures on cerebro-spinal fever to these cases of meningococcaemia, which "may precede, follow, or occur without meningeal infection." He quotes some interesting observations by Netter and Dopfer. Dopfer's observation is that whereas before the war 66 per cent. of the cases of meningococcal meningitis were infected with the meningococcus Type A (Gordon's I and III types) a change has taken place, so that now the parameningococcus or Type B (Gordon's II and IV) is responsible for an equal, if not a larger, number of the cases. Netter<sup>3</sup> comments that this observation may be correlated with an increased incidence of meningococcaemia, and meningococcal manifestations in the skin, joints, and eyes.

The organism in our case, a meningococcus of Type II (British classification) or Type B (French classification) certainly showed no particular affinity for the cerebro-spinal system, as it was more than four months before the

spinal fluid became infected. It is interesting that the organism disappeared from the blood stream before this terminal meningeal infection took place.

We shall not here embark on a discussion of the mutability or fixity to type of these bacteria beyond noting that the organism as obtained from the blood stream was a hardier, coarser-growing type than that obtained later from the cerebro-spinal fluid. Such a change might, of course, be merely a temporary or fluctuating variation due to environmental conditions, particularly as the hardier qualities were quickly lost on subculture.

The case emphasizes the necessity for bearing in mind the possibility of a change in the nature of meningococcal infections.

## THE CHEMOTHERAPY OF RECENT EXPERIMENTAL WOUND INFECTIONS:

WITH SPECIAL REFERENCE TO THE ACTION OF  
ACRIFLAVINE.\*

BY

C. H. BROWNING AND R. GULBRANSEN.

(From the Pathological Department of the University and the Western Infirmary, Glasgow.)

THE question whether localized infections can or cannot be treated effectively by means of antiseptics applied to the infected area appears still to be a subject for argument. Animal experiment might be expected to yield a decisive answer. But a difficulty, as most workers have found (for example, see Watson Cheyne, Bassett-Smith, and Edmunds<sup>1</sup>), is the tendency for infections in small animals to become generalized and so to escape beyond the range of action of the antiseptic. In the case of mice inoculated intraperitoneally with organisms so highly invasive as virulent pneumococci, we<sup>2</sup> have shown that it is possible to effect cure sometimes by means of intraperitoneal injections of various antiseptics; but this line of work has not been pursued owing to the difficulty in controlling the virulence of the infection. Recently, the infection of experimental wounds in guinea-pigs with a virulent culture of *B. diphtheriae* has been recommended as a test object for investigating the therapeutic properties of antiseptics (Braun,<sup>3</sup> Feiler<sup>4</sup>). In the first place, there is very little tendency for the infection to become generalized; and secondly, when a highly virulent culture is employed the results are decisive, since the unmodified infection is rapidly fatal.

#### METHODS.

Guinea-pigs of about 200 to 250 grams weight were used. An area of the skin of the abdomen was shaved. When the animal was under the influence of a general anaesthetic two parallel linear cuts, each measuring about 1.75 cm. and at a distance apart of 0.8 cm., were made through the skin in the direction of the long axis of the body, care being taken not to incise the deeper tissues. Then, by means of a stout wire bent into a loop, the strip of skin between the cuts and also the skin for about 1 cm. on either side of the incisions was raised from the deeper structures, so that pockets were produced; there was, of course, very little bleeding from the wound. About a quarter of a well grown forty-eight hours' agar slope culture of *B. diphtheriae* was then rubbed into the wound and the pockets. The animals were left for varying periods and were then treated. Treatment consisted in placing the animal on its back and pouring slowly into the wound 1 c.cm. of a watery solution of the substance the action of which was to be investigated, the wound and pockets being meanwhile swabbed out with a small

\* Work done with the support of the Medical Research Council.

pledget of cotton-wool, like a throat swab, which had previously been soaked for several minutes in the same solution as that used to treat the wound. This procedure lasted for a minute and a quarter. At the end of this time any fluid which had not been absorbed by the tissue was allowed to drain away and the surrounding skin was swabbed dry. The wounds received no further treatment. (In the case of the experiments with bipp, as much of the undiluted mixture as would adhere to a swab was used to treat the surfaces of the wound and the pockets, any excess being wiped off the skin.)

The experiments were not considered as concluded until at least three weeks after the date of inoculation.

#### SERIES I.

Infection with highly virulent *B. diphtheriae* (strain A, recently isolated): designed to test whether effective treatment is possible. Twelve animals were inoculated. After intervals of 45, 75, and 120 minutes respectively two animals were treated with 1 per cent. watery solution of neutral acriflavine. At each period, by way of control, two animals were treated by washing the wounds similarly with 0.85 per cent. NaCl solution.

**Results.**—The animals treated with acriflavine (with one exception—treated after 14 hours—which died eight days after inoculation without having shown signs of illness previously) remained alive and well. The six controls\* treated with saline were all dead within forty-eight hours.

#### SERIES II.

Infection with highly virulent *B. diphtheriae* (strain A, recently isolated); in order to compare the therapeutic action of acriflavine and phenol and to ascertain the effect of treatment with 5 per cent. NaCl solution. The interval between inoculation and treatment was one hour.

##### Results.

Reagent used to Treat Wound.	No. of Animals treated.	Result.
Neutral acriflavine { 1 in 1,000 . . . . .	2	All survived.
1 in 400 . . . . .	2	
1 in 100 . . . . .	2	
Carbolic acid 1 in 20 . . . . .	2	1* died 4 days later.
NaCl solution, 5 per cent. . . . .	2	Both* died within 48 hours.
NaCl solution, 0.85 per cent. . . . .	2	Both* died within 48 hours.

#### SERIES III.

A distinctly less virulent diphtheria infection (strain A, some time after isolation) than that in Series I and II. Interval between inoculation and treatment, one hour.

##### Results.

Reagent used to Treat Wound.	No. of Animals treated.	Result.
Neutral acriflavine { 1 in 2,500 . . . . .	1	All survived.
1 in 2,000 . . . . .	1	
1 in 1,500 . . . . .	1	
1 in 1,000 . . . . .	1	
1 in 500 . . . . .	1	
1 in 250 . . . . .	1	
Carbolic acid { 1 in 100 . . . . .	1	Died* within 72 hours.
1 in 75 . . . . .	1	Died* within 72 hours.
1 in 50 . . . . .	1	Survived.
Bipp . . . . .	2	1* died within 72 hours. 1* died after 9 days.
NaCl solution, 5 per cent. . . . .	2	1* died within 72 hours. 1 died after 14 days.

#### SERIES IV.

A distinctly less virulent diphtheria infection (strain C) than that in Series III. Interval between inoculation and treatment, eighty minutes.

##### Results.

Reagent used to Treat Wound.	No. of Animals treated.	Result.
Neutral acriflavine { 1 in 5,000 . . . . .	1	All survived.
1 in 2,500 . . . . .	1	
1 in 1,000 . . . . .	1	
1 in 500 . . . . .	1	
1 in 200 . . . . .	1	
Carbolic acid { 1 in 20 . . . . .	1	Survived.
1 in 40 . . . . .	1	Died in 13 days.
Bipp . . . . .	1	Died* within 72 hours.
NaCl solution, 5 per cent. . . . .	1	Died* in 75 hours.
NaCl solution, 0.85 per cent. . . . .	1	Died* in 80 hours.

\* Indicates that in these animals the suprarenal bodies were haemorrhagic, which is the most constant change found in death due to diphtheria infection.

There is little doubt that the late deaths were mainly the result of the infection, although the characteristic changes were absent at this stage, since most of these animals had been obviously ill for several days after inoculation.

The results show that in highly virulent infections (Series I and II) treatment of the wound with neutral acriflavine in dilutions down to 1 in 1,000 (the highest dilution tested) regularly caused survival (one animal only out of twelve died, after an interval of eight days). Treatment with 5 per cent. carbolic acid caused only a protraction of the infection. Treatment with 5 or 0.85 per cent. salt solution was entirely without effect under these conditions as the animals so treated died within forty-eight hours after inoculation.

In somewhat less virulent infections (Series III and IV) acriflavine in dilutions down to 1 in 2,500 caused survival. Carbolic acid solution had a distinct effect. Thus in Series III carbolic acid in a concentration of 1 in 50 led to survival, but animals treated with concentrations of 1 in 75 and 1 in 100 died acutely; in Series IV, which had the least virulent infection of the four, treatment with concentrations of 1 in 40 and 1 in 80 carbolic acid led to survival or marked protraction of the infection. Of three animals treated with bipp all died with typical *post-mortem* findings; in only one was the illness protracted. In the latter two series, out of four animals treated with saline, one (belonging to Series III, treated with 5 per cent. NaCl solution) died after fourteen days; the rest died acutely.

In still less virulent infections only a proportion of animals treated with saline die acutely in two to five days with typical *post-mortem* appearances; the rest may fail to become ill or may recover, some after being obviously ill; of the latter a proportion die after several weeks. Thus in addition to the above experiments several series were inoculated with the Park-Williams strain No. 8 of *B. diphtheriae*,† which, in spite of its high capacity for producing toxin *in vitro*, is of comparatively low virulence when young cultures are tested in animals. All of the nineteen guinea-pigs treated with acriflavine 1 in 100 at intervals of forty to ninety minutes after inoculation with this strain survived. Of the nineteen controls whose wounds were washed out at similar intervals with 0.85 per cent. saline eight died (42 per cent.). This result also is in support of the efficacy of treatment with the antiseptic as compared with mere washing of the wounds.

Of course, the results recorded here do not affect the question of appropriate operative procedures in the treatment of infected wounds, nor do they bear upon the need for antitoxin treatment in cases of diphtheria in man.

The efficacy of acriflavine (trypaflavine) in the therapy of experimental wound diphtheria has also been demonstrated by Feiler<sup>4</sup> and by Reinhardt.<sup>5</sup> It has been shown that this effect cannot be ascribed to destruction of diphtheria toxin present in the culture used for inoculation by neutral acriflavine, but is the result of destruction of the bacilli (Braun<sup>1</sup>).

† For this culture we are indebted to Dr. R. A. O'Brien, Wellcome Research Laboratories.

## CONCLUSIONS.

1. The results of treating recent experimental wounds opening into the subcutaneous tissue which have been infected with highly virulent diphtheria bacilli prove the efficiency of antiseptic therapy. Under the conditions investigated brief treatment with a suitable antiseptic (neutral acriflavine in concentrations of 1 in 100 to 1 in 1,000) has caused survival of practically 100 per cent. of the infected animals. On the other hand, salt solution (either 0.85 or 5 per cent. NaCl) similarly applied did not prevent in any instance the acute illness and fatal termination.

2. When acriflavine and carbolic acid are compared, it is found that the ratio of their therapeutic effectiveness exceeds 50 to 1. This conforms with estimates of their relative potency previously arrived at by us<sup>3</sup> by other methods.

3. In less virulent infections the therapeutic action of carbolic acid is evident. But bipp showed practically no action even in the latter; it would appear that the therapeutic effect of this mixture, so frequently commented on by clinical observers, must depend on some property other than an antiseptic one.

## THE DECLINE OF LITHOLAPAXY.

BY

ALFRED HOOTON, C.I.E., M.R.C.S., L.R.C.P.,  
 MAJOR-GENERAL I.M.S., POONA, INDIA.

In the *Principles and Practice of Surgery* (1914), by Dr. A. P. C. Ashhurst, the following passage occurs:

"The operation of litholapaxy is not now in general use because the mortality of cutting operations is less than when Bigelow's operation was introduced, and because recurrence of stone formation is frequent (18 per cent.), either because all the fragments are not removed at first, or because urinary obstruction or vesical infection are not relieved. But the primary mortality is very low (5 per cent.), and the operation may be done under local anaesthesia in very debilitated subjects. It is best reserved for such patients, provided no cystitis is present."

The book is an American one, and, though presumably representative of practice in the United States, does not necessarily speak for British surgery. But this is, in any case, strange doctrine for the country of Bigelow, and there is reason to believe that the same view is gaining ground amongst British surgeons. A short time ago, for instance, I met a keen and highly qualified junior surgeon in charge of an Indian hospital, who was doing no crushing, and told me that the operation of litholapaxy was now regarded as obsolete at home. He had spent several years in resident appointments at well known English hospitals; and one is continually hearing the same view from men who have recently passed through British medical schools. It is for this reason that I have thought it worth while to write the following note.

Thirty years ago my old chief, Mr. F. A. Southam, was using lithotrites successfully in the Manchester Royal Infirmary, and there was no doubt in those days, so far as I remember, as to litholapaxy being the operation of choice for stone in the bladder. The chief arguments now brought against it appear to be that suprapubic lithotomy can be done with nearly as great safety, that litholapaxy is difficult to learn and dangerous when performed by inexperienced operators, and that there are more recurrences after it than after lithotomy.

A statistical comparison of the results of the two operations is hardly possible in India, where for the most part only the bad cases are dealt with by the cutting operation, and I have never seen an effective comparison of British figures, which might presumably be obtainable. The impression is widely prevalent in India, however, that litholapaxy in skilled hands is much the less dangerous opera-

tion, and our figures speak for themselves, and still more emphatically if it is admitted, as we all contend, that, contrary to the impression at home, our cases on the average are far less promising than those which come to the English hospitals. We have a very large proportion of large stones and septic bladders to deal with, and we consider, moreover, that the idea which seems to prevail at home that Indian patients in general bear operation better than Europeans is entirely erroneous. It remains to be said that suprapubic lithotomy is not without its dangers. A very little disturbance of the cave of Retzius may lead to disastrous consequences.

The frequency of recurrence after litholapaxy is much exaggerated. Under proper conditions recurrences should be very rare. Experience of my own and other people's work is that they are quite infrequent, though it is unfortunately impossible to put up figures in proof of this statement. A fair test of the general result of the operation is its reputation with the public. The Indian cultivator, who furnishes the great majority of our up-country patients, is an acute judge of the practical results of surgery, as shown, for instance, in his appreciation of Bassini's operation for hernia. As regards litholapaxy, he made up his mind long ago, and there is no surer way of emptying one's hospital than by reverting to a cutting operation where crushing has formerly been in vogue. There is not only the escape from the knife but the early discharge from hospital to be considered, and it is, of course, quite common for children who have been relieved of small stones by the lithotrite in the morning to be running about in the afternoon. It is, I think one may say, the opinion of an overwhelming majority of Indian surgeons that litholapaxy in proper hands has great advantages over any of the cutting operations in all but a small percentage of complicated cases, and it would be a very great pity if the contrary view were to be generally accepted and taught in the British schools, particularly in the case of men who are destined to practise in the East. I append a list of cases treated in four representative hospitals of this Presidency. Many more extensive series have appeared in the pages of the *BRITISH MEDICAL JOURNAL*, but they seem to have passed too readily into oblivion.

I.—Cases operated on by Lieut.-Colonel R. W. Anthony, F.R.C.S.E., during three years and three months in 1920-25 at the Civil Hospital at Hyderabad, Sind.

	Cases.	Deaths.
Litholapaxy (including 30 perineal litholapaxies) ...	1,253	7*
Suprapubic lithotomy ...	11	3
Perineal lithotomy ...	0	0

\* Three others "discharged otherwise"—probably died.

This is the most noted centre for vesical calculus in this Presidency, and has dealt with an average of 464 cases a year during the last ten years. Colonel Anthony says that he looks on every case of stone as one for litholapaxy if it can be done, and that there are very few cases in which it cannot, given an experienced operator. If it is impossible to crush by the urethra in the ordinary way he performs perineal litholapaxy. He crushes stones up to about 6 ounces, and hardly ever gets one that he cannot deal with, either by the ordinary or perineal route, by means of a large lithotrite or a hammer. He apparently never does perineal lithotomy now, and only performs suprapubic lithotomy primarily from choice in patients with enlarged prostates. Thus, as he points out, his suprapubic cases must be taken largely as failed litholapaxies of a complicated nature—for example, cases in which the bladder has an hour-glass shape, or processes like the finger of a glove containing stone, or encysted stone; or those rare accidents where the lithotrite has jammed, or perforation of the bladder has accidentally occurred.

II.—Cases operated on by Lieut.-Colonel T. S. Novis, F.R.C.S., at the Jamshejee Jeejeebhoy Hospital, Bombay, from June 14th, 1920, to December 31st, 1925.

	Cases.	Deaths.
Litholapaxy ...	114	1
Perineal litholapaxy ...	0	0
Suprapubic lithotomy ...	17	5
Perineal lithotomy ...	2	0

Note.—Of the deaths from suprapubic lithotomy, two were complicated with prostatectomy, and two developed pneumonia.

This is the chief general hospital in Bombay, and associated with the Grant Medical College. Here, also, litholapaxy is the routine operation, the contraindications quoted by Colonel Novis being very large or very hard stones, very soft putty-like stones, stricture, enlarged prostate, extensive kidney disease, and bladder growth of any considerable size. He lays stress on a routine cystoscopic examination of the bladder, both before operation, to exclude the possibility of encystment of the stone or other complications, and immediately after, or at any rate before discharge,

to make sure no fragment is left behind. The series quoted includes two cases of haemorrhage, in both of which suprapubic cystotomy had to be performed, and in one an extraperitoneal rupture was found to exist. Both these recovered. Here also the suprapubic cases are the worst and cannot be quoted for purposes of comparison.

III.—Cases operated on by Mr. A. K. Dalal, F.R.C.S., also at the Jani-setjee Jeejeebhoy Hospital, from November 29th, 1921, to March 22nd, 1923.

	Cases.	Deaths.
Litholapaxy ...	13	0
Suprapubic lithotomy ...	8	0
Perineal lithotomy ...	1	0

IV.—Cases operated on by Lieut.-Colonel A. J. Vernon Betts, M.B., at the Civil Hospital, Nasik, from November 1st, 1922, to October 31st, 1923.

	Cases.	Deaths.
Litholapaxy ...	58	0
Perineal lithotomy ...	3	1
Suprapubic lithotomy ...	5	0
Perineal lithotomy ...	0	0

This is taken as a typical civil hospital with a fairly active surgical practice. The series is a small one because these are the only results for which he can personally vouch.

V.—Cases operated on by Lieut.-Colonel A. Hooton, I.M.S., at the Agency Hospital, Rajkot, from December 5th, 1920, to March 23rd, 1923.

	Cases.	Deaths.
Litholapaxy ...	94	2
Perineal litholapaxy ...	5	0
Suprapubic lithotomy ...	15	0
Perineal lithotomy ...	1	1

This also is taken as a typical civil hospital with a fairly active surgical practice.

Perineal lithotomy still has its uses (contrary to the dictum of some of the textbooks), though the occasions are not frequent. Encysted stones, or abscess associated with them, about the neck of the bladder, call for one or other of the perineal operations.

## A METHOD OF DETERMINING THE PATENCY OF THE FALLOPIAN TUBES BY X RAYS.

BY

EVERARD WILLIAMS, M.D., M.R.C.P.,

OBSTETRIC REGISTRAR AND TUTOR,  
AND

RUSSELL REYNOLDS, M.B.,

PHYSICIAN IN CHARGE, DEPARTMENT OF RADIOLOGY AND ELECTRO-THERAPEUTICS,  
CHARING CROSS HOSPITAL.

The investigation of certain cases of sterility involves an examination of the Fallopian tubes in order to ascertain whether they are patent. It was felt that the present

(Figs. 1 and 2). A simple apparatus (made by Allen and Hanburys) was devised for the introduction of bismuth or barium emulsion into the uterine cavity (Fig 3). The point we wish to emphasize is that the emulsion is merely dropped into the uterine cavity and is not forced in under pressure. An anaesthetic is not necessary.

The question how the particles find their way into the tubes naturally arises. The observations that better shadows are obtained if the patient has had an anaesthetic (with the accompanying post-anaesthetic retching and vomiting), and that Bond placed the particles in the vagina and not in the uterus, suggested the possibility of aspiration being the motive power, though the original conception was that the ciliated epithelium swept the particles up. To settle the point certain experiments

FIG. 1.—Shows shadow in uterine cavity and distal portions of tubes and amniotic extremities. (A normal case.)

FIG. 2.—Shows shadows similar to Fig. 1. A normal case, ten hours after barium introduction.

methods of testing this patency are unsatisfactory, in that they are all open to the objection of causing an increased intruterine and intratubal pressure, in cases in which, from their very nature, it is anticipated that organisms may be lurking in the uterus or the tubes, and that it would therefore be safer to employ some method of investigation which does not depend upon creating a positive intrauterine or intratubal pressure.

A method suggested itself to one of us (E. W.) after reading of Bond's experiment of the recovery, at a laparotomy, of coloured particles from the peritoneal cavity of rabbits, after their previous introduction into the vagina. If particles opaque to x rays be substituted for coloured particles, a radiogram should indicate their passage through the tube. A method was tried in which particles of barium sulphate were insufflated into the cervix uteri, and x-ray photographs were taken twenty-four, forty-eight, and seventy-two hours later. Several cases of normal multiparous women were thus investigated. The photographs did not give a shadow sufficiently dense to be really satisfactory, and at Dr. Russell Reynolds's suggestion an emulsion of barium sulphate was tried, and gave good results, particularly when general anaesthesia was employed

were performed upon animals in which bismuth emulsion was introduced into the vagina alternately with and without ligation of the Fallopian tubes.

These experiments showed that the particles do not find their way up the Fallopian tubes unless there is a free communication between the tube and the peritoneal cavity. This suggests that a purely mechanical factor, such as aspiration, is more likely to be responsible than anything in the nature of ciliary activity. If the tubal ostia are patent, the emulsion travels from the uterus to the tube, and therefore, if the shadow is seen in the tube at all, it indicates patency of that tube. In the course of seventy-two hours the whole of the bismuth or barium has disappeared. In no instance have any after-effects been complained of by the patients.

Another point worthy of mention is that the shadow in the body of the uterus gives a much more accurate estimation of the size of the uterine cavity, in cases of infantile uterus or other maldevelopment, than does bimanual

FIG. 3.—Syringe and cannula.

examination; the latter only reveals the gross size of the uterus, which may be masked by the presence of a fibroid or an unduly thick wall.

We have used the method to determine the patency of a tubo after salpingostomy for tubal mole (impossible by the other methods if the opposite tube is patent), and also in a case which proved to be an instance of a double uterus. The value of the method as an aid to diagnosis in other difficult cases is obvious.

We believe also that the demonstration of the passage of particles from the uterine cavity to the fimbriated extremity of the Fallopian tube throws some light on the origin of ascending infections of the genital tract, and perhaps also on that of endometrioma of the ovary and the deposit of fragments of exfoliating endometrium on the pelvic peritoneum and surface of the ovary.

In conclusion, we wish to express our thanks to Dr. Eden and Dr. Cuthbert Lockyer for permission to investigate cases in the hospital.

## THE HEART IN CHRONIC TOXAEMIA.

BY

H. CLULOW NIXON, M.D. EDIN.,

PHYSICIAN, ROYAL MINERAL WATER HOSPITAL, BATH.

DURING the examination of patients suffering from infective arthritis and fibrositis, an attempt has been made to estimate the degree of involvement of the heart and arterial system in this form of chronic toxæmia. These types of cases can very frequently be traced to a local focus of infection, which most usually arises in or around the teeth, tonsils, or nasal accessory sinuses, but may later involve the colon, gall bladder, etc. Less frequently the source of infection is in the uro-genital tracts.

This paper is concerned principally with those streptococcal infections associated with cases classified as "rheumatic," or more properly "infective." No attempt has been made to include hearts poisoned—first, by acute diseases such as rheumatic fever, typhoid fever, dysentery, or malaria; secondly, by endogenous means, as, for example, excessive thyroid action or chronic kidney disease; thirdly, by an exogenous poison such as alcohol; or, lastly, by syphilis. Toxins may influence any property of heart muscle, altering its rhythm, excitability, conductivity, contractility, or toxicity. They act chiefly on those tissues which govern rhythm through stimulation of the accelerator nerves, causing sinus tachycardia, and also on the tonicity of the muscle; to a lesser extent they influence the excitability, and to a still smaller the conductivity and contractility. They may directly affect the tissue of the heart by their local action, or organisms in other parts of the body may affect the heart by their toxins. From the fact that they are set free within the body in varying quantities their effect on the heart will also vary in degree from time to time. Apparently in streptococcal infection of low virility extending over many years, the heart does not become profoundly poisoned as in Graves's disease or chronic nephritis, where myocardial degeneration is common.

That the heart has partaken of the general toxæmia may be established by physical examination.

1. *Palpation*.—Estimate first the position of the apex beat. In many cases it is found in the nipple line or outside it. Secondly, note its character. It is often diffused and rather feeble and slapping; if it is the latter, it has to be differentiated from mitral stenosis, where the left ventricle is unfilled, or from myocardial degeneration, where the left ventricle is weak. There is no left ventricular hypertrophy, except when aortic incompetence, increased blood pressure, or chronic Bright's disease exists as a complication.

2. *Percussion*.—By careful percussion the left border of the heart can be found to have moved outwards, measuring more than 31 in. from the mid-sternal line. Increase in transverse diameter may therefore amount to 1½ in. to 2 in., denoting myocardial weakness. The poisoned muscle fibres having lost their tonicity, there is an increase of pressure from a larger flow of blood into the heart during diastole, and an incomplete emptying is the result; in this way dilatation of the left ventricle takes place.

3. *Auscultation*.—Particular attention is to be paid—

(a) To the character of the first sound at the apex. It may be muffled and distant, or it may be short and sharp, or actually it

may be loud. If it is short and sharp, it must be remembered that the muscle may be inflamed, fatigued, or degenerated.

(b) To the absence or presence of a murmur. In the early stages no murmur is audible; later, when dilatation takes place, a mitral systolic murmur can be heard—that is, a murmur of relative incompetence, due to stretching of the circular muscular fibres around the auriculo-ventricular valves. This murmur is soft, diminishing in character, and is not conducted beyond the mid-axillary line. It is louder after inspiration and on lying down, disappearing on full expiration, cessation of respiration, and with exercise.

The toxic heart is a large heart with relative increase in the oblique diameter, and its long axis is horizontal. It is soft and atonic, with the transverse diameter measuring more when lying than standing. On examination by x rays it is seen to move up and down in the manner of a concertina, and its size, determined by percussion, can be verified. It is a heart of low efficiency. On standing up after resting, the normal difference of rate of 7 to 15 beats a minute is markedly increased. On exercise, the heart unduly accelerates, and returns slowly to normal; often several minutes elapse before it has regained its original rate; this should be accomplished in two minutes. During exercise the blood pressure sometimes fails to rise with the pulse rate, or even may actually fall.

### SYMPTOMS.

Certain general symptoms which are associated with any form of toxæmia may be present—for example, loss of weight and of the feeling of well-being. The skin is often yellow, and may present a papular rash. There is often some mental depression and irritability of temper. Vasomotor and nervous instability is prominent, and hence tremulousness, precordial pain, palpitation, breathlessness, giddiness, exhaustion, faintness, cold feet and hands, numbness, local sweating and flushing, dermatographism, or myotonic irritability may appear. Morning anorexia, nausea associated with gastro-intestinal disturbance (for example, offensive stools and flatulence), intestinal stasis and chronic constipation, headache and derangement of the endocrine glands, and sleeplessness are sometimes present. Night symptoms are frequent.

Taking particularly those symptoms most often present the commonest are:

1. *Palpitation*.—Tachycardia often makes its appearance at an early stage of the infection, and its severity bears some relation to the degree of toxæmia. An increase of 10 to 50 beats a minute represents the usual extent of the heart's acceleration. Quite frequently the symptom passes unnoticed by the patient. It is a sinus tachycardia.

2. *Breathlessness* on even slight exertion, such as going upstairs or climbing a moderate incline, is a common complaint.

3. *Exhaustion* is a troublesome symptom which causes patients more discomfort than increased effort.

4. *Precordial Pain*.—Pain is referred to an area situated usually below the left nipple, and is commonest in women. It must be looked upon as a vasomotor neurosis, or secondary angina caused by the circulation of toxins which increase the excitability of the nervous system and sensitivity of the reflex arc, so that mild stimuli are sufficient to produce an exaggerated impression. The pain is more usual when the patient is resting and in the evening. The attack may be precipitated by emotion or other reflex cause. Hyperalgesic areas of skin and referred pain follow the usual paths as in primary angina.

*The Condition of the Arterial System*.—Although admittedly in many cases systolic blood pressure is found considerably raised, yet more frequently sphygmomanometric readings are distinctly lower than normal. In 45 cases observed the following were the results:

Systolic Blood Pressure.					Cases.				
Between 120 and 130					Cases.				
Between 120 and 130	120	130	...	1	Between 130 and 140	130	140	...	9
" 120 " 130	120	130	...	4	" 130 " 140	130	140	...	10
" 130 " 140	130	140	...	4	" 140 " 150	140	150	...	8
" 140 " 150	140	150	...	1	" 150 " 160	150	160	...	6

William Russell has drawn attention to the fact that, irrespective of the pulse wave, arteries contract and relax, due to the fibres of the muscular coat being placed transversely. This variation in size indicates the degree of hypermyotonia and hypomyotonia, and is determined by

shins and backs of the hands was striking, it being shiny, thin, and stretched. Later, on November 10th, an extensive purpuric eruption developed on the legs; the petechiae being so numerous as to be almost confluent. This, however, was not associated with any further trouble, and indeed from this point the convalescence was uninterrupted, and to-day the patient enjoys his normal good health.

Accidents of this kind are probably extremely rare, but it is not difficult to imagine a chain of events similar to those described above occurring where ultra-violet light is used without medical advice and in a similar fashion—drowsiness, sleep, and in consequence an unduly prolonged exposure. The mishap may serve as a warning against the irregular use of a special method of treatment. Nothing, however, that has been said should be taken as discrediting a remedy of great value when properly employed.

Whether the phenomena related above should be considered representative or not we cannot say. There are at least some features which seem peculiar, and to them attention may be drawn. First, that an interval of days elapsed between the original burn and the subsequent dermatitis; secondly, the severity of the toxæmia, considerable enough indeed to place the patient's life in jeopardy and to give occasion for considerable alarm as to the outcome; and, thirdly, the fact that the skin on the back was affected, although this part of the body was not directly exposed to the ultra-violet light.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### ASIATIC BILHARZIA DISEASE.

DURING the past twelve months nine cases of this disease have been reported by me on the frontiers of British India and China, where its existence had previously been unsuspected. Other cases have no doubt escaped notice.

As to the African form of bilharzia, there seems very little doubt that, originating in Egypt, the affection travelled south until at the present time the whole continent is involved and the disease has spread to the islands of the New World. The question is whether the more deadly Asiatic variety, starting as it probably did in the Far East, has gradually spread west, and whether the confines of British India are the present westerly limit. If so, how long will they remain so?

As regards Yunnan itself, there are two large freshwater lakes at Yunnan, Fu and Tali Fu, which are possibly breeding grounds for *Oncomelania hupensis*, etc. In its northern watershed arise Burmese rivers—for instance, the Shweli and other branches of the Irrawaddy, the Salween, etc., while on the eastern side the Yangtse-Kiang takes origin. If the sources of these rivers are continually being reinfected there appears to be no limit to the spread of the disease through Burma. It would appear that preventive measures should be directed towards two main channels—namely, to get rid of the disease in human beings by vigorous treatment with tartar emetic, after Christopher's method; and to destroy the intermediate host—the snail. Both have their advocates, but the former appears the weakest link in the chain to attack, and one which offers the most promising results. At the same time much research work on the carrier snail awaits the enthusiast.

#### LITERATURE.

Case of Asiatic Schistosomiasis, *Proc. Roy. Soc. Med.*, vol. xvii, No. 6, August, 1924.  
Human Schistosomiasis in India, *Journ. of Trop. Med. and Hygiene*, December 15th, 1924.

#### MYELOGENOUS LEUKAEMIA IN A NEGRO: FAILURE OF TRYPARSAMIDE.

The case here recorded is of interest for the following reasons: (1) The rarity, in a district where the spleen is frequently enlarged from such diseases as malaria, trypanosomiasis, and bilharziasis, to find this sign due to leukaemia. (2) The fact that massive doses of an arsenic-rich compound tryparsamide failed to affect appreciably the

course of the disease. The patient received a total of 12 grams (representing 3 grams or 46 grains of arsenic) by intravenous injection within a fortnight. (3) In spite of this there was no amblyopia, although similar doses employed in the treatment of cases of trypanosomiasis with central nervous infection would have almost certainly produced very serious visual disturbance. As an example may be quoted the case of an adult male who three years ago showed trypanosomes in the cerebro-spinal fluid, but who after treatment with a similar quantity of tryparsamide in the same interval of time became completely blind, but is still in excellent health with a normal cerebro-spinal fluid.

This tolerance is the more remarkable in that retinal changes and haemorrhages are commonly found in the leukaemias, and incidentally supports the view that sleeping sickness patients are predisposed by the toxin of the disease itself to the development of arsenical neuritis of the optic nerve. The following are the clinical and haematological details:

Saidi, a male aged 20, complained of fullness of the abdomen, attended with dyspepsia and some shortness of breath. The condition had developed gradually and there was no history of haemorrhages or other symptoms. He was well nourished, though obviously anaemic and somewhat flabby. No oedema or swellings of lymphoid tissue were detected, but the spleen was enlarged and filled almost the entire left side of the abdomen. Its margin was hard and nodular.

A blood count on July 24th, 1924, was as follows:

Red blood cells*	...	...	2,850,000 per c.mm.
Haemoglobin	...	...	65 per cent.
Colour index	...	...	1.1
White blood cells	...	...	485,000 per c.mm.
Polymorphs	...	...	39 per cent.
Myelocytes	...	...	33 "
Large mononuclears	...	...	19 "
Lymphocytes	...	...	5 "
Eosinophils	...	...	3 "
Mast cells	...	...	1 "

\* There were the usual signs of deterioration together with normoblasts and megaloblasts.

After a week's treatment by rest, the white blood cells, on July 30th, numbered 346,000 per c.mm. Tryparsamide (2 grams of a 40 per cent. solution) was injected intravenously. On August 2nd the white cells numbered 390,000 per c.mm. Tryparsamide (3 grams) injected. On August 6th there were 454,000 white cells per c.mm. Tryparsamide (4 grams) injected. On August 13th the white cells numbered 339,000 per c.mm. Tryparsamide (3 grams) injected. On August 30th the white cells numbered 450,000 per c.mm.

The patient's symptoms were not alleviated, and he refused to remain longer in hospital.

#### RUPTURE OF SCLEROSSED ARTERY.

I DESIRE to put on record the following case. The sketch showing the rupture is from an x-ray photograph.

A man, aged 48, received a heavy blow on the back of the right leg from some falling timber. When I saw him there was extensive bruising of the whole calf. This was treated in the ordinary way and was later massaged. The massago rapidly reduced the discoloration and swelling, with the exception of an area near the middle of the leg and just behind the internal margin of the tibia. A swelling of the size and shape of an egg persisted in this area;

it was much paler than the surrounding parts and was fluctuant. The swelling did not pulsate; it was diagnosed to be a deep haematoma. On the eighth day it was aspirated and bright red blood was removed. Firm pressure was then applied, but the swelling re-formed. Some days later it was again aspirated. A small notch could then be felt in the margin of the tibia. Pressure was again applied, but the swelling once more returned, on this occasion to a lesser degree. The leg was x-rayed on the sixteenth day, with the result shown.

There is an irregularity in the line of the posterior surface of the tibia, corresponding to the notch. The posterior tibial artery is in a fairly advanced condition of arterio-sclerosis; at the level of the notch the artery has been driven against the bone and has broken. The fracture of the artery is shown faintly but distinctly. The swelling ultimately subsided and there was no apparent interference with the circulation in the foot.

Birkenhead.

APRIL 11, 1925]

# ENDOCRINE THERAPY.

## Reports of Societies.

A SPECIAL discussion took place at the Royal Society of Medicine on March 31st on endocrine therapy. Sir WILLIAM HALE-WHITE presided.

A Rational Basis for the Treatment.

Dr. W. LANGDON BROWN said that endocrine therapy might have as its object the replacement of a deficient internal secretion, in which case they were on a sound ground with thyroid extract and insulin, on less sure ground with parathyroid and pituitary extracts. But it might ground with other glandular preparations. But it might also have as its object the employment of some extract for its pharmacological action, such as adrenaline simply for its vaso-constrictor effect or pituitrin for its stimulating effect on plain muscle. He would also include under endocrine therapy the use of other drugs which, by their influence on the endocrine glands, enabled those glands to carry out more successfully their normal function; he instanced iodine medication in diseases of the thyroid. As to methods of administration, apart from thyroid extract and (less constantly) pituitary extracts, the effect of oral administration was very uncertain. Nasal administration had met with a certain degree of success in the treatment of diabetes insipidus by pituitrin. Of rectal or intravenous injection, adrenalin, pituitrin, and insulin could readily produce powerful effects. Grafting and transplantation methods were still on their trial. It would appear that such grafts were treated, so that they would appear as foreign bodies and become absorbed, so that their effect was only temporary. Dr. Langdon Brown went on to attribute some of the recent disagreement between the physiologist and the clinician on endocrine therapy to non-realization by some laboratory workers of the urgency of the problem which a sick man presented, and to the uncritical enthusiasm and undue suggestibility of some observers at the bedside. Indiscriminate poly-glandular therapy had led certain laboratory workers to challenge the very existence of the endocrine system, yet others had recently obtained results which supported this conception. Agnosticism had even been carried to the point of doubting whether the observed pharmacological actions of adrenalin and pituitrin had any relation to the functions of the structures from which those extracts were prepared. He could hardly believe that the body was so ill designed as the widest application of all the endocrines and was the easiest in practice. Parathyroid extract was of doubtful value of great service in tetany and gastric ulcer. Adrenalin was of little if any use in substitution therapy; it was of great use for its local effect on blood vessels and for its effect on plain muscle. Pituitary extract was of doubtful value, though it might occasionally alleviate Frohlich's syndrome and adiposis dolorosa. Insulin was of value and as a temporary cardiac stimulant. He had a number of proved cases that if insulin was once given it must be continued for the rest of life. He had a number of patients who came under early treatment with it, and who were keeping free from glycosuria, with a normal blood sugar, although insulin had been discontinued for periods varying from three months to over a year. The existence of an ovarian hormone he regarded as proved, and it should not be beyond the wit of man to prepare a reliable extract. It was doubtful whether the present commercial preparations were active, but he had seen great benefit in thymic asthma and in a case of epileptiform seizures accompanied by temporary swelling of the thyroid. In conclusion, Dr. Langdon Brown said that he doubted whether any orchitic extract was effective.

## A Protest against Some Claims of "Clinical Endocrinology."

Professor SWALE VINCENT declared that the present boom in endocrine therapy was an evil of the same general nature as the indiscriminate sale of patent medicines. But whereas in the latter case it was the members of the general public who were so continually duped by the vendor of the drug, in the former the distressing spectacle was to be witnessed of hundreds or thousands of medical men being enjoined into prescribing preparations which were nearly always of doubtful value and were often quite inactive in health or disease. He recited a list of the various extracts now obtainable, also the various combinations of these preparations there was no evidence that any effects whatever were produced when they were given in the ordinary way by the mouth—unless in such quantities as to serve as foods! He thought there was justification for regarding with great suspicion any report that a pharmacologically inactive substance was of therapeutic value. Discussing certain preparations singly, he said that, of course, there was no need to emphasize the value of thyroid preparations in myxoedema and in rheumatism, rickets, degrees of hypothyroidism and in other conditions these preparations might also be useful on the general principle that a drug which stimulated the chemical activity of the whole body might be applicable in a variety of morbid conditions. The results of parathyroid medication were still very uncertain. Commercial preparations of ovary and parathyroid at present on the market were, according to the majority of competent observers, physiologically inactive, and in all probability useless as therapeutic agents. It had never been demonstrated in a satisfactory manner that treatment by pituitary extracts had any effect in remedying the symptoms thought to be due to pituitary insufficiency. Posterior lobe preparations were useful as drugs in the treatment of diabetes insipidus and to aid contractions of the uterus, but these uses had no relation to any known function of the organ, and were not instances of a substitution therapy. Adrenin was a very useful drug, but it would be rash to affirm that its usefulness was directly related to anything known about the functions of the adrenal body or the chromophil tissues. Extracts of ovary and testis produced no noticeable effects in health or disease when taken by the mouth; when given subcutaneously the commercial preparations appeared to be for the most part inactive, and at the best only produced a slight irritant effect. Insulin ranked with thyroid substitution as a means of instituting a very valuable substitution therapy. Thus there were only two clear instances of preparations—the thyroid and the pancreas—with which it was possible to effect such a therapy; and only one of these—the thyroid—was known to produce effects when swallowed. Out of some two dozen preparations of different organs and tissues, sold by manufacturing druggists and prescribed by clinical endocrinologists to be administered in the ordinary way by the mouth, only one was of proved value. Physicians who continued to prescribe preparations for the use of which there was no scientific basis and no sound clinical evidence were guilty of conduct unworthy of modern medicine.

Dr. LEONARD WILLIAMS asked whether Professor Vincent's rather comprehensive condemnation was based on clinical experience, or on grounds purely theoretical; but the chairman would not allow the question to be pursued at that stage of the debate.

Endocrine Preparations in Veterinary Practice.

Mr. LESLIE PRUGH, speaking of veterinary practice, said that pituitary extract was employed largely in obstetric work, and thyroid extract in a variety of conditions. Several disorders of the function of milk production in cattle were known and pituitary extract had been employed. Its general effect was to empty the udder more quickly, though the total milk yield was neither increased nor diminished. Thyroid extract had proved useful in the endocrine upset following cases in which the corpus luteum,

instead of atrophying after a period of activity, persisted, and thus prevented the uterine contractions that occurred at oestrus and that proved so helpful in eliminating retained discharges or infective material. He had attempted to bring about the expulsion of a mummified foetus from the uterus by the use of pituitrin and other glandular preparations, but in every case he had been compelled to dislodge the corpus luteum of pregnancy before obtaining this result.

#### *Effect of Certain Extracts on Obesity and Growth.*

Dr. H. GARDINER-HILL brought forward the results of some work undertaken in the Medical Unit at St. Thomas's Hospital on the treatment of obesity in adolescents and adults by a combination of thyroid and pituitary extracts. The adolescent cases showed, besides obesity, disturbances of growth and bone development, and disordered genital function and carbohydrate metabolism. The adult cases occurred chiefly in women following childbirth or at the menopause, or their obesity, first noticed at puberty, then became exaggerated. The cases were treated by a combination of thyroid and whole-gland pituitary extracts, given by the mouth in increasing doses. Thyroid extract alone, when swallowed, produced good results in some cases, but others showed thyroid intolerance, and this difficulty seemed to be overcome by the combined method. The effect of treatment was to render more normal the carbohydrate tolerance, and in many cases a reduction in weight was effected. Certain cases of defective growth were treated by thyroid and pituitary extracts. Three children who had a definite endocrine factor and were considerably undergrown for their age showed a distinct improvement in the rate of growth; six others, in whom no definite endocrine factor was recognized, but in whom growth was below the average and infantile characteristics persisted, also improved in rate of growth and in other respects under treatment. Many photographs and charts illustrating the progress of the cases were exhibited.

#### *Organotherapy of the Testis.*

Mr. KENNETH WALKER confined himself to discussing the therapy of the testis. The effort to obtain results from the oral administration of testicular extract had failed, and this had led to the use of testicular grafts. He referred to the work of Voronoff, who had now made some fifty or sixty transplants into the human subject from the higher apes, and claimed to have obtained valuable results. The grafts had been undertaken for various conditions—cunuchoidism, senility, neurasthenia, and sexual neurosis—and the chief benefit was said to be in the direction of improvement in the general health, increase of mental and muscular vigour, and stimulation of hair growth. Improvement was less definite in cases grafted for impotence or sexual neurosis. Other workers in this field had preferred to use human transplants, and had derived their material from newly executed criminals, patients dying of accidents, and cases of ectopia testis in which the removal of the misplaced organ was justified. It was from this last source that the speaker had himself obtained his grafts. The technique of transplantation was not difficult. Personally, he thought that Voronoff's use of a serous cavity like that of the tunica vaginalis for implantation was the best. Mr. Walker believed that vascularization and survival of the graft was an actual fact. At the same time, a steady atrophy of the engrafted material no doubt occurred, and the actual life of the transplant was, he thought, considerably shorter than that claimed for it by Voronoff. He would feel happy if he could be sure that complete atrophy did not occur within eighteen months. This, however, did not necessarily mean that at the end of that period all benefit was lost. A graft might stimulate the growth of existing testicular tissue, or the hormone supplied by the graft might tide the patient over a critical period until compensatory changes in other endocrine glands succeeded in restoring the endocrine balance. In conclusion, he said a few words about vasoligation as a means of stimulating the activity of the testis. Those familiar with Steinach's experiments on aged rats must certainly be impressed by the results of vasoligation. In

human beings the results of the operation had been less certain. In many cases there had been no benefit; in some the general health and mental vigour of the patient had improved, and in a few cases the results had been still more striking. The speaker had performed Steinach's operation in some fifteen cases, and, although it was difficult to eliminate the element of suggestion, he believed that in at least half of them an improvement in general health and mental vigour had taken place. He was particularly inclined to recommend the operation in the treatment of that hopeless malady of later life, paralysis agitans.

[At this point the discussion was adjourned for a short time, and on the resumption the chair was taken by Dr. LANGDON BROWN.]

#### *Experimental Effects of Glandular Extracts.*

Mr. J. E. R. McDONAGH described some researches on the effects of glandular extracts on animals; the object was to ascertain the effects on the blood and organs and so arrive at a basis for the chemotherapeutic employment of the drugs in man. Adrenaline caused the protein particles in the plasma to increase in number and then to go into solution, and this dual action of conduction and dehydration caused constriction of capillaries with rise of blood pressure. Insulin caused hydration of the protein particles, and adrenaline proved to be an antidote by dispersing the hydrated particles. When protein particles increased in size they were likely to be precipitated in capillaries; if in the cerebral ones, fits and convulsions ending in coma ensued; if in the lungs the consequence was the pulmonary form of shock. Adrenaline was not powerful enough in these conditions, and should be substituted by injecting glucose intravenously and oxygen subcutaneously. Adrenaline was apt to fail as a styptic because its later action of dehydration retarded coagulation. Thyroxin caused a slower dehydration of protein particles, and therefore was more valuable in the chronic stages of disease, when the protein particles increased in size and became too independent. When the particles gradually increased in size, thyroxin could break them up. Insulin was an excellent antidote against any powerful dehydrator. An acute bacterial infection might cause such profound dehydration as to call for insulin as the drug best suited to bring back to the colloidal state those protein particles which were passing into true solution. Insulin could also be employed with advantage in cases of anaemia associated with a great destruction of red corpuscles. The remaining extract with which he had experimented was ageratin (testicular extract), whose clinical behaviour suggested that it might be a phosphatide, related to cephaline. It protected an animal against infections, interfered with the antigenic action of the organic extract in the Wassermann reaction, and reduced the precipitating effect of a positively reacting serum. When once in the system this extract should prove useful as a protection against the invasion of parasite and chemical reagents.

#### *Other Speakers.*

Dr. H. CRICHTON MILLER pointed out the importance of the endocrine gland secretions from the subjective aspect, for which line of study, of course, animal subjects were not available. There was great need for evidence as to the action of the drugs on the human subject, and in this connexion he mentioned that a drug house of high standing which desired to withhold its name had placed a series of tablets for experimental trial at the disposal of the Tavistock Clinic, all labelled simply by letters of the alphabet, some of them for men and some for women, and the members of the staff and certain other medical colleagues had volunteered to consume them and report upon the results.

Dr. M. B. RAY gave an account of some ancient by-ways in pharmacy, such as the old belief in certain witch-hazels. He believed that the ductless glands exerted a powerful effect on the body metabolism, and he pictured various types of cases which were held to be significant of deficiency in one or other of these respects. He stressed particularly the relation of goitre to rheumatism in young

girls. In localities where goitre was endemic rheumatic fever, cardiac rheumatism, and rheumatoid arthritis had an abnormally high incidence.

#### Openers' Replies.

Dr. LANGDON BROWN thought that the discussion had proved that there was now less difference than was the case a few years ago between the clinical point of view and that of the laboratory. Some laboratory work was being done which confirmed what had already been indicated by clinical observers from their own bedside experience. He was anxious to ascertain whether Professor Swale Vincent, who had criticized the theory on the present occasion, still took the agnostic view with regard to pituitary gland secretion. He considered Mr. Leslie Pugh's contribution to the discussion of great interest. The effect of the stimulating action of the pituitary body on the mechanism of milk production in the cow confirmed observations which had been made on the human subject with regard to the sympathetic nervous system and the ductless glands.

Professor SWALE VINCENT, in reply to this question from the chair, said that to his mind the fact that one extracted an active juice from pituitary gland meant nothing more than that such a juice could be extracted. There was a similar lack of exact knowledge concerning the adrenals. With regard to the observations of MacKenzie Wallis on the blood sugar curves, he confessed that he was not favourably impressed by them, and the same was true of the data given by Professor Dixon which had also been quoted. [Dr. Langdon Brown had remarked that MacKenzie Wallis had shown that the blood sugar curve in the glycosuria of pregnancy was the same as that of pituitary glycosuria, and that Dixon had shown that the injection of ovarian extract caused the immediate secretion of pituitrin into the cerebro-spinal fluid.] Often the physiological material used was too delicate, and the doses, such as one in 500 million, were too small for conclusions to be based upon them. He contended that an attitude of greater scepticism was called for in the professing physician with regard to these matters. One was always in a position of entire ignorance as to what would have happened to a case if a certain treatment had not been adopted, and until the normal curve and incidence of a disorder was known it was dangerous to assume that a given remedy had been efficient, and it was particularly dangerous to give a mixture and attribute the result to one component of it. There were many pitfalls in therapeutics generally, and endocrinology supplied more of these than any other department.

#### EXPERIMENTAL ANASTOMOSIS OF NERVES.

A MEETING of the Section of Surgery of the Royal Society of Medicine was held on April 1st, with the President, Mr. H. J. PATERSON, in the chair.

Sir CHARLES BALLANCE, with Mr. LIONEL COLLEDGE and Dr. LIONEL BAILEY, presented a paper on the results of experimental anastomosis of nerves. Sir Charles Ballance first referred to the difficulty often met with in nerve injuries from war wounds when so considerable a length of nerve had been destroyed that end-to-end suture became impossible. In such cases he performed double lateral implantation of the injured nerve into a healthy nerve in the vicinity. Cases were quoted in which a very fair functional result had been attained by this procedure. In one case the middle trunk of the cervical plexus was thus implanted into the upper. Six years later the arm was wasted, but, in spite of the fact that no treatment had been given since operation, a faradic response was obtained in all the muscles of the arm and forearm except the extensores proprii pollicis and communes digitorum. In another case a gap of five and a half inches in the median nerve was bridged by double lateral implantation into the ulnar. The median intrinsics were wonderfully restored and the man was able to work. The technique of double lateral implantation was described. Three methods had been employed: (1) implantation of the cut proximal and distal ends of the nerve into small transverse incisions in the

healthy nerve, each anastomosis being held in place by a suture; (2) implantation by pressing the two cut ends into longitudinal incisions into the healthy nerve, the junctions being secured by a "varnish" of muscle fibres wrapped around; (3) was the same as (2) with the addition of one stitch at each junction for added security. The speaker next passed on to the experimental work done on paralysis of the vocal cord and the results obtained by the suture of the distal end of the recurrent laryngeal nerve to other nerves in the vicinity. This experimental work, as well as that on suture of the paralysed facial to other nerves, has already been described at length in papers by Sir Charles Ballance<sup>1</sup> and Mr. Lionel Colledge<sup>2</sup> in the *BRITISH MEDICAL JOURNAL*. The experimental work in monkeys showed that the best results in the case of the facial nerve were obtained by anastomosis with the glossopharyngeal, possibly owing to the very close relationship of the motor nuclei of the two nerves as well as their association through Jacobson's nerve and the ansa of Haller. In the case of the vocal cord slight success to the extent of restoring the tone of the paralysed cord was obtained by recurrent laryngeal-descendens noni anastomosis, but very striking results were obtained by anastomosis of the recurrent laryngeal to the phrenic nerve. In the latter case the movement of the previously paralysed cord during quiet respiration became actually increased as compared with the opposite side.

At the conclusion of the paper, which was profusely illustrated by lantern slides and diagrams, cinematograph films illustrating the results obtained in monkeys in facial and vocal cord palsy by various anastomoses were shown by Dr. BAILEY and Mr. COLLEDGE. In both series the results were very striking, and the cinematographic pictures of the larynx showing the cords in rhythmical movement during respiration formed a specially beautiful demonstration.

The paper was commented on briefly by the PRESIDENT, and by Mr. W. G. SPENCER and Mr. H. S. SOUTAR.

#### PAROXYSMAL RHINORRHOEA.

A MEETING of the Section of Laryngology of the Royal Society of Medicine, in which members of other Sections were also invited to take part, was held on April 3rd, with Dr. A. LOGAN TURNER in the chair, in order to discuss the subject of paroxysmal rhinorrhoea.

Dr. J. FREEMAN, director of the department of clinical bacteriology at St. Mary's Hospital, who opened the discussion, said that hay fever was only one symptom of a condition. The inherent character of hay fever was the reaction of the mucous membrane of a man who was sensitive to pollen when he met that pollen. Similarly, dust from the coat of a horse upset the "horse asthmatic," dust from a cat's fur the "cat asthmatic," and so on. But these substances could also reach the sensitive person through the blood as well as by the atmosphere. Hay fever was not a nasal disease; eye, throat, skin, and constitutional symptoms were also present. In the artificially prepared disease an urticarial rash was produced by bringing pollen into contact with a scratch, abdominal symptoms of the pollen were swallowed with food, pruritus and if it were injected up the rectum, angio-neurotic oedema, asthma, and urticaria if injected into a vein. If the serum of a hay fever patient were put into a normal person and his skin scratched and pollen applied, a dermal reaction would be produced. The symptoms of protein idiopathy might include paroxysmal rhinitis ("nasal asthma"), hay fever, horse asthma (cat asthma, etc.), asthma, urticaria, eczema, ichthyosis, angio-neurotic oedema, food sickness (vomiting and diarrhoea), epilepsy, migraine, paroxysmal arthritis, paroxysmal colitis or nephritis, and insect fevers. The causal chain comprised the hereditary factor, protein irritants, nervous factors (which were often strongly prominent), and trauma; angio-neurotic oedema appeared at a previously damaged part of the body. Some psychical affair often started an attack, such as witnessing a motor accident or a dog fight. He held that protein idiopathy was not an abnormal nervous condition. In regard to diagnosis and treatment, of recent

<sup>1</sup> *BRITISH MEDICAL JOURNAL*, August 30th, 1924, p. 349.

<sup>2</sup> *Ibid.*, March 21st, 1925, p. 547.

years he had come to the conclusion that to treat the condition by dodging the irritant and immunizing was impossible. In testing the skin reaction the thing that mattered most was easily missed, and the skin reaction did not correspond to the intensity of the symptoms. The actual substance was much better for testing than any of the extracts employed for that purpose; the accommodation of a consulting room, however, was not unlimited, yet, as regards fungi, which were common irritants, there were sixty-three varieties of dry rot alone. The immunologist, the neurologist, and the laryngologist must treat the condition from their own points of view.

Mr. A. BROWN KELLY, speaking as a rhinologist, said that the old term, "vasomotor rhinitis," was, in spite of criticisms that had been made, a correct term, as in a note in the *BRITISH MEDICAL JOURNAL* of the previous week<sup>1</sup> it had been pointed out that the suffix "itis" meant disease, and not inflammation. A nasal crisis was characterized by its not being due to infection, although it resembled a severe cold. It was marked by suddenness of onset and cessation. On probing, there was often sensitiveness of the nasal mucosa, particularly on the septum and at the anterior ends of the inferior turbinates, and the mucosa did not readily subside under cocaine. When treating nasal polypi it had to be kept in mind that the radical cure of polypi was impossible so long as vasomotor rhinitis was present. Heredity was an important causal element; a neurotic stock was particularly prone to the condition. A period of mental or physical tension often preceded an attack of vasomotor rhinitis. Toxaemia might lead to vasomotor disturbances; intestinal toxaemia was most frequent, but septic foci in the nasal sinuses and tonsils were also common.

Dr. JAMES ADAM said that paroxysmal rhinitis connoted two things—catarrh and spasm. In general they were due to toxaemia, caused by dietetic and hygienic errors. On examining 800 cases that had come within his experience, 42 per cent. began in the first decade of life, and of these over 21 per cent. gave a history of eczema. The cause of asthma was a toxaemia from carbohydrate excess; 75 per cent. of cases were cured by attention to diet and exercise, with a weekly mercurial purge. Anaphylaxis was not the most important element in asthma.

Dr. MARGARET C. TOD said that Dr. Logan Turner and Dr. J. S. FRASER had allowed her to go over all the cases of asthma treated in the ear and throat department of the Edinburgh Royal Infirmary from 1907 to 1924. There were 507 cases of asthma, and 315 operations had been performed for their relief. She had sent a simple form to each of these patients to inquire as to the results of operative treatment, and 173 had sent replies, representing 226 operations, some patients having had more than one operation; of these, 19 were cured, 76 improved, and 78 were no better. The prognosis was best in young adults. A striking result was the success of removal of tonsils and adenoids, and the comparative failure of cauterization; in most of the cases Francis's area had been the area cauterized. The conclusions were that the cure of asthma could not be promised by operation, but where the airway was blocked or septic foci were present the symptoms would be relieved.

Dr. MILLAIS CULPIN said that from the psychologist's point of view paroxysmal rhinorrhoea was only part of one big picture. As regards the nervous element in it, it was only by making a careful and skilled examination that a neurologist could say whether a person was nervous or not. The symptoms were often associated with phobias.

Sir JAMES DUNDAS-GRANT said he had found that the upper posterior part of the nasal septum was the most sensitive. Polypi sometimes produced asthmatic attacks, which were relieved by their removal.

Mr. FRANK COKE said that the persons who suffered from this condition were ordinary people, not neurasthenics. Cauterization of the septum sometimes relieved, as did the removal of tonsils and adenoids. Possibly anaphylaxis was due to some colloidal change in the blood.

Mr. T. B. LAYTON and Mr. ARDINGTON GIBB gave interesting accounts of personal experiences. Mr. C. A. PARKER

noted the polishing of mahogany in furniture making as among the causes.

Dr. A. WYLIE said that the majority of cases were due to an auto-intoxication, and the general health should be treated. The most valuable drug was calomel, and gr. 1/10 every day would reduce the blood pressure. Mr. P. WATSON-WILLIAMS said that in the treatment of paroxysmal rhinorrhoea he used, locally, a 10 per cent. solution of cocaine combined with atropine gr. 1/100. Dr. J. S. FRASER remarked that this subject eminently lent itself to team work; a clear idea on it could not be arrived at by any one man.

## CYSTOSCOPY.

At a meeting of the Brighton and Sussex Medical-Chirurgical Society held on April 2nd, Dr. E. F. MAYNARD, the President, in the chair, Mr. F. E. FEILDEN read a paper on cystoscopy.

Mr. Feilden said that the best cystoscope on the market was one of German or American manufacture. It was advisable to become accustomed to an instrument of known magnification, and to endeavour to distend the bladder with a uniform quantity of fluid. Cystoscopy was one of the most important methods of exploration in urological surgery. In cases of vesical calculus cystoscopy gave a direct diagnosis and indicated the correct method to adopt for the removal of the calculus. As to whether an anaesthetic was required or not depended upon the circumstances of the case; usually no anaesthetic was required. Tubercle bacilli, or *B. coli* might be found in the urine without any lesion of the kidney being present. Residual urine, a trabeculated bladder, and no evidence of urethral obstruction, usually indicated some lesion of the cord. The experiments of Dyko and Maybury seemed to indicate clearly the caution necessary in pyelography and irrigation of the kidney pelvis; cystitis due to the gonococcus was not common. In estimating the functional activity of the kidneys the most reliable test was the urea concentration one, but estimation of the blood cholesterol content appeared to be also of value. Too often cases of frequency of micturition were treated on expectant lines; early cystoscopy might prevent irreparable damage to the bladder wall. Meatoscopy was useful in the diagnosis of certain cases, but this was not so in the majority. New growth, stone, and tubercle were more common on the right side; this might be due to the fact that there were more structures crossing the right ureter than the left. A radiogram of a patient with a ureteric loop in situ was a valuable means of differentiating between a calculus in the ureter and a calcareous gland adjacent to the ureter. Not infrequently the failure of a nephropexy was due to the kidney not being fixed at a sufficiently high level. A double ureter should suggest other abnormalities in the urinary tract. In catheterizing healthy ureters when the bladder was known to be infected there was little likelihood of conveying the infection to the ureters. Nephrectomy in cases of haematuria of unknown origin was only justifiable when the bleeding was unilateral, or when, by its frequency or amount, it endangered the patient's life or seriously interfered with his occupation. Lastly, Mr. Feilden said that in selected cases diathermy through the cystoscope was a most successful procedure, obviating the prolonged convalescence that was often associated with an open operation.

### Malignant Growths of the Bladder.

Mr. FITZMAURICE-KELLY showed a case of epithelioma of the bladder. The patient, a woman aged 54, had no symptoms till September 26th, 1923, when a sudden large haemorrhage from the bladder occurred. This was followed by retention due to clots, necessitating catheterization. Cystoscopy on September 27th showed a papillomatous growth on the anterior wall of the bladder. At the operation on September 29th a hard flat ulcer was found just above the papilloma, and the whole thickness of the bladder wall bearing the growths with an area about 3/4 inch around was resected, and the bladder closed with drainage. Two applications of radium, 140 mg. in twelve hours,

<sup>1</sup> BRITISH MEDICAL JOURNAL, March 22nd, p. 621.

were made on October 6th and 7th through the suprapubic opening. Now, eighteen months after the operation, the patient remained well and free from symptoms.

Dr. H. M. GALT showed in this connexion some microscopical slides of malignant papilloma of the bladder, malignant papilloma of the bladder across the pedicle, simple epithelial papilloma of the bladder, and ova of bilharzia haematobia in the bladder wall.

Dr. C. G. WHOMLOW showed some radiograms taken with the Potter-Bucky diaphragm.

Dr. GEORGE MORGAN described a case of varicose veins of the prostate with severe attacks of haematuria every three months lasting two to three days, which cleared up when capsules containing turpentine (2 minims) were taken every four hours. He also quoted a case which was diagnosed by x rays as a small stone in the ureter, but which, on cystoscopy, was shown to be an old calcareous gland.

Dr. H. M. GALT thought that all villous growths of the bladder were clinically malignant and that the malignancy was purely a matter of degree; it was a waste of time to remove a small piece of growth for pathological report.

Mr. FITZMAURICE-KELLY said that cystoscopy should be performed under a local anaesthetic in males; in females an anaesthetic was not required. In cases of severe cystitis he thought that spinal anaesthesia should be employed also. In advanced tuberculous kidney, when it was important to estimate the function of the other kidney, spinal anaesthesia was very valuable when using the indigo carmine test for renal efficiency. In renal lavage it was quite safe to use a pressure of 15 inches—that is, below secretory pressure. Where there was difficulty in diagnosis between stone and tumour, a ureteric catheter could be used as a probe. Bleeding from one kidney might be caused by malignant disease; it was very important to diagnose the condition and operate at once. For this pyelography should be employed.

### TREATMENT OF VESICAL PAPILLOMA.

At the meeting of the Liverpool Medical Institution on March 5th the members of the Manchester Medical Society were guests and contributed the programme.

Mr. J. B. MACALPINE read a paper on the treatment of vesical papilloma by cystoscopic methods, combined with diathermy, illustrating it by lantern slides. He outlined his own technique, laying emphasis on the desirability of general anaesthesia in order to increase the length of the treatments, so diminishing the number of them required. In America and on the Continent, where local anaesthetics were in use, the number of treatments often exceeded twelve, whilst in his own practice it was very rare for more than four sittings to be required. Further, the burning of the base of the growth was painful, and therefore might be shirked when local anaesthesia was employed. The pre-urethral approach was, he thought, universally accepted as the method of choice in all cases where the growth was small, or where little recurrences were spotted early. With extended experience, it was possible to employ it for papillomata of greater size. Even when a large growth filled a considerable portion of the bladder and rendered the examination and treatment difficult, it was usually possible for the experienced cystoscopist to select a spot where the current could be applied with perfect safety; and even though the visibility became poor as the result of cloudiness of the medium much progress could be made, with the result that in three weeks' time, when the bladder was inspected again, the growth would have shrunk and treatment could be continued under direct vision. Such treatment had proved eminently satisfactory in his experience. The results were excellent if the cases were systematically followed up for a period of two or more years. To this end the patients had to be communicated with before their treatments became due, and when many patients were simultaneously under treatment this involved a properly organized "follow-up." Such a system was illustrated in

the lecture. Re-examination cystoscopies should be made at first over a period of three months and later at six-monthly intervals. This, together with the obtaining of the cases at the first onset of haematuria, was the secret of good results. Recurrences when quite early were easily and successfully treated. It was an interesting fact that return growths rarely took place on the site of the primary growth later than three months from the last treatment.

### MELANOMATA.

At a pathological meeting on March 19th at the Liverpool Medical Institution, Mr. H. C. W. NUTTALL read a short paper on melanomata. After discussing the normal distribution of melanin pigment and its relation to the pathological process, a brief description of the clinical characters and course followed. The danger arising from irritation of moles was emphasized, and the extreme rapidity of their recurrence after incomplete excision was pointed out. The histological appearances and the difficulty of deciding whether the growths were benign or malignant was next touched upon, and an analysis of thirty-five cases illustrated many of the points discussed. Mr. Nuttall reviewed the question of the origin of melanomata from either epidermal or mesoblastic cells, and showed that recent work was strongly in favour of an epidermal origin. A brief survey of the phylogeny and functions of the melanin pigment cell inclined to the view that, in white races at any rate, it was probably a vestigial structure, and therefore more liable to atypical growth.

Dr. ROBY JONES and Professor ERNEST GLYNN also read a short paper on abnormal blood groups among forty medical students, mainly discovered by cross-agglutination tests, but also by absorption tests. In the former case the serums and corpuscles of each student were tested against those of the remainder, 1,600 tests being performed by the macroscopic method, each in five dilutions. The cross-agglutination test showed 7 per cent. Group I, 30 per cent. Group II, 17 per cent. Group III, 46 per cent. Group IV. Abnormal agglutinations occurred in moderately high titre with four serums, three being Group IV, and four sets of corpuscles, three being Group IV. The blood from one Group IV student behaved abnormally both in its serums and corpuscles. Another abnormal Group IV serum was discovered by the absorption test. The relatively large percentage of Group IV students whose corpuscles agglutinated slightly was striking, and of considerable importance in blood transfusion.

### PLYMOUTH MEDICAL SOCIETY.

At a clinical meeting of the Plymouth Medical Society held on March 17th, the President, Mr. C. L. LANDER, showed a case of splenomegalic polycythaemia of many years' duration. He read a note on the relation of herpes to chicken-pox. Several members had noticed instances of the two diseases occurring together, and their further relation to poliomyelitis was considered. Mr. VELLACOTT showed a tumour of the lower part of the thigh in a man aged 27, who gave a history of six years' duration. A cystic tumour had been removed elsewhere two years before. It was generally held that the present condition was sarcomatous, and such it appeared to be to the naked eye on examination of a fragment, removed next day for microscopic report. Mr. KENNEDY showed a young man with an ulcer of the tongue, suffering also from tuberculous epidiidymitis and chronic phthisis; it was an example of the solitary tuberculous ulcer of the tongue. Mr. RIDDEL described a case of puerperal septicaemia, which recovered after many rigors with temperature 107°. The uterine condition quickly settled down after a large tube had been placed in the uterus to allow of frequent encol irrigations, but septic thrombosed piles seemed to provide the source of infection which led to the rigors with hyperpyrexia. Blood cultures were negative. Other cases were shown or discussed by Messrs. ROLSTON, ERIC WILSON, and HAMILTON WHITEFORD.

## Revelus.

### ANTIMALARIAL REMEDIES.

THE volume entitled *Chininum: Scriptioes Collectae Anno MCMXXIII editae*,<sup>1</sup> which is issued by the Dutch bureau for increasing the use of quinine, consists of translations into English of twenty-five articles on the medicinal use of quinine published in 1923. The articles contain a large amount of information concerning the production and use of quinine, and those dealing with the world supply and consumption of quinine are particularly interesting.

Figures are given of the cinchona bark production of 110 plantations which together supply about 90 per cent. of the Dutch bark. These plantations produced in 1923 bark containing 534,624 kilos of quinine sulphate; only 470,000 kilos were used in that year, and, in addition, the bark stored in Java and Amsterdam at the end of the year represented a further quantity of 239,680 kilos of quinine sulphate. These figures taken together seem to show clearly that the plantations are producing more quinine than the world can buy, and yet their present production does not represent their maximum output, for the harvest of bark has been restricted in many plantations since 1921. These facts reveal a deplorable state of affairs, since they show that the commercial demand for quinine is comparatively low, is indeed below the present output, while yet the world's real need for quinine is enormously in excess of the supply. The reason for this is, of course, that the vast malaria-stricken populations of Eastern countries which urgently need quinine live in such dire poverty that they cannot afford to buy the drug.

The true demand for quinine is indicated by figures quoted elsewhere in the volume. It was estimated that in 1920 the deaths from malaria in British India numbered 1,300,000, and that in 1923 there were 10,000,000 cases of malaria in Russia. Tables of the malaria mortality in Italy for the last half-century show the extraordinary benefit that can be produced in a malarial population by the efficient distribution of quinine. At the end of last century the deaths from malaria in Italy numbered about 150,000 a year; they have fallen steadily ever since the passing, at the commencement of this century, of laws providing for the State distribution of quinine, and deaths from malaria now total only about 3,000 a year.

The volume therefore provides very clear proof that the present production of quinine is in excess of the commercial demand, but that millions are suffering from malaria owing to lack of quinine. There appear to be only two possible remedies—either the provision of quinine in some cheaper form, or else extensive State assistance in the distribution of quinine. The latter solution is simple, and naturally commends itself to the producers of quinine. The former is much more difficult, and the only likely way of reducing the cost of antimalarial remedies seems to be the supply of some satisfactory preparation of the mixed alkaloids in a partially purified state. This policy, as is pointed out by Dr. Hofman in an article on the cinchona febrifuge, has already been tried by the Java planters. The policy was abandoned, however, because the supply of pure quinine to the relatively rich European populations is a much more attractive commercial proposition than is the endeavour to meet the needs of impoverished Oriental peoples with a cheaper mixture of the alkaloids.

How to supply the native populations for which this country is responsible with antimalarial remedies at a minimal cost is, however, one of the most obvious and urgent of imperial problems. The expenses of a thorough examination of this problem on a large scale would be trivial compared to the enormous interests involved. We are glad to note that this is one of the problems which the Malaria Commission of the League of Nations Health Organization proposes to investigate.

<sup>1</sup> *Chininum: Scriptioes Collectae Anno MCMXXIII editae*. Amsterdam: Bureau tot Bevordering van het Kinine-gebruik. 48, De Wittenkade. 1924. (Roy. 8vo, pp. 134; illustrated. Presented by the Bureau.)

### EXAMINATION OF THE BLOOD.

THE book by Professor LOVELL GULLAND and Dr. ALEXANDER GOODALL entitled *The Blood: a Guide to its Examination and to the Diagnosis and Treatment of its Diseases* has reached a third edition.<sup>2</sup> First published in 1912, this book, with its straightforward account of the diseases and diseased conditions of the blood and blood-forming organs, became a favourite with both students and practitioners because of its clear description, its lavish illustrations, and its eminently practical character.

Since 1912 not a few new doctrines about the origin of blood diseases have been proclaimed: towards these the authors have for the most part adopted a cautious attitude, and have resisted the temptation to be carried away by dialectics which have no immediate practical bearing. The latest edition remains a treatise on the histological, pathological, and clinical aspects of blood diseases. The authors do not go into details of chemical or serological tests, but give references to special works on these subjects. In addition to the twenty-nine figures in the text, the book is now illustrated with sixteen beautiful coloured plates.

### OPHTHALMOLOGICAL TEXTBOOKS.

THE issue of a fifth edition of MAY and WORTH'S *Manual of Diseases of the Eye*<sup>3</sup> is some measure of its usefulness. The first English edition was published in 1906, and besides the five editions there have been eight reprints; of the last edition alone there were four.

The book deserves the recognition it has obtained. It deals with diseases of the eye in so clear and straightforward a way that the student cannot fail to be informed and have his clinical interest stimulated by the study of its pages. Further, it is well balanced and inclusive in its statement of conditions and the means whereby these may be treated, and therefore it will remain a convenient book of reference after student days. Not the least valuable feature of the book is the profusion of illustrations; wherever a figure can usefully supplement the letterpress an illustration is provided. In this new edition the book has been carefully revised, and some new matter added. Happily this has been done without increasing the size of the book. The most noteworthy change is in the chapter on vaccines in ophthalmology, written by Dr. S. H. Browning. In that chapter of ten pages there is as succinct and faithful an account of clinical pathology and vaccine therapy in relation to the eyes as could be desired. The chapters on the ocular manifestations of general disease and on general ocular therapeutics are very good. The publishers inform us that the eleventh American edition was published simultaneously with the fifth English, that translations have appeared in Spanish, French, Italian, Dutch, German, Japanese, and Chinese, and that altogether 150,000 copies have been issued.

It is only about a couple of years ago that we noticed the last edition of the translations into English of FUCHS'S *Text-book of Ophthalmology*, and it speaks well for its vitality and popularity that in so short a time a new edition<sup>4</sup> should be published. The book is so well known that no lengthy notice of it is needed; anyone who seriously thinks of taking up the study of ophthalmology buys Fuchs's textbook as a matter of course. The changes in the new edition are not numerous, but the whole text has been revised and brought up to date by the inclusion of the latest work on the subject. Some of the illustrations have been redrawn and a few new ones have been added. Among

<sup>2</sup> *The Blood: a Guide to its Examination and to the Diagnosis and Treatment of its Diseases*. By G. Lovell Gulland, O.M.G., M.A., B.Sc., M.D., F.R.C.P.E., and Alexander Goodall, M.D., F.R.C.P.E. Third edition. Edinburgh: W. Green and Son, Ltd. 1925. (Roy. 8vo, pp. xvi + 429; 29 figures, 16 plates. 25s. net.)

<sup>3</sup> *A Manual of Diseases of the Eye*. By Charles H. May, M.D., New York, and Claud Worth, F.R.C.S.Eng. Fifth edition. London: Baillière, Tindall and Cox. 1924. (Demy 8vo, pp. viii + 460; 337 figures, 22 plates. 15s. net.)

<sup>4</sup> *Text-book of Ophthalmology*. By Hofrat Ernst Fuchs. Authorized translation from the twelfth German edition; completely revised and reset, with numerous additions specially supplied by the author and otherwise much enlarged by Alexander Duane, M.D. Eighth edition, revised. London: J. B. Lippincott Company. 1925. (Med. 8vo, pp. xv + 937; 455 figures. 42s. net.)

the improvements we note that additions have been made in the sections which deal with renal retinitis and diplopia, the neurology of the eye movements, and the untoward effects that may follow the use of serums and vaccines. The index also has undergone revision. The work is certainly one of the most authoritative on the subject with which it deals, and will, we are sure, continue to deserve the popularity it has for so many years enjoyed.

### INSANITY AND LAW.

DRS. H. DOUGLAS SINGER and WILLIAM O. KROHN have conjointly written a book entitled *Insanity and Law: A Treatise on Forensic Psychiatry*,<sup>5</sup> which is intended to provide the physician with a better knowledge of legal practice and ideals, and the lawyer with fuller information about mental disease. The authors feel that there is no fundamental conflict between medicine and law, and that difficulties disappear and co-operation becomes possible when each understands the other, for the views are really complementary. It is with the hope of contributing to this understanding that this book has been written. The first part furnishes a description of the various types of reaction and the different forms of mental disease; the second deals with insanity in its legal aspects, the subject being considered much more fully than in the ordinary textbook. Among the questions discussed are the legal definition of insanity; guardianship; insanity in relation to contracts, marriage, tort, criminal responsibility, and testamentary capacity; the physician in court; and the possible reforms in legal procedure.

The American laws in relation to insanity differ considerably from those in this country, and the book will thus be found most useful by American psychiatrists and lawyers. The lack of uniformity of legal procedure in the various American States makes the whole matter very complicated, and the authors point out that in no other subject have the laws enacted by the different States been so divergent and conflicting. On the whole we gain the impression that the procedures for commitment in cases of insanity are more elaborate and irksome than in England, and the possibilities of voluntary treatment do not appear to have been sufficiently realized or explored. Thus the authors express the view that while, theoretically, voluntary admission to institutions for the insane is an important step in advance, as a practical procedure it does not work well, except in comparatively few instances. Experience of the voluntary boarder system in this country has, of course, led to an entirely contrary view. The book is a balanced and judicial contribution to legal psychiatry, and it is obvious that the authors are thoroughly conversant with their subject in all its aspects.

### FOUR BOOKS ON BACTERIOLOGY.

BACTERIOLOGISTS, as a class, are prolific authors, and we have here to direct the attention of readers to four new books on the science of bacteriology. Literary fertility is to some extent a natural consequence of the bacteriologist's particular calling. As a rule, early in his career he engages in research work which becomes published in scientific journals, thereby initiating him, while still youthful, into the dignities of authorship. But we do not wish to imply that writing becomes a habit and ends in the appearance of books, for other reasons are to be found for this plenitude. It must be remembered that bacteriology is a new science, continually cultivating its territory and enlarging its dominions. Fresh statements of opinion are necessary, therefore, at comparatively short periods: former views must be revised, inaccuracies corrected, and knowledge recently gained must be incorporated in new books, or in later editions of successful textbooks, which began perhaps as slender brochures but grow eventually to imposing volumes. Because, also, of the relative instability of this science it happens frequently that those whose duty it is to teach bacteriology find themselves in disagreement with the

grammar of contemporary textbooks or feel that it might be presented in a more convincing or a more convenient fashion; the books do not contain quite the doctrines they themselves would teach and the facts they would wish their students to learn. Hints of this uneasiness are ill concealed in the humblest of prefaces, and in others the author boldly admits this to be the justification for the appearance of his book.

Influences such as these are responsible for the prominence which bacteriology gains in publishers' catalogues. We believe that the science benefits from the generous collection of books from which students may choose, and that such books as the four we have lately received form a useful addition to the bacteriological library.

The book which Professor T. J. MACKIE and Dr. J. E. MCCARTNEY have written is entitled *An Introduction to Practical Bacteriology*,<sup>6</sup> and is intended as a guide to bacteriological laboratory work. It is useful to have a book which deals only with the technique of laboratory work. Textbooks which set out to provide a complete exposition of such a science as this rarely give sufficiently detailed advice as to how various tests should be performed. In the descriptive textbook the thread of the narrative must not be interrupted too frequently by paragraphs of small print, and therefore the practical instructions become condensed in a preliminary chapter or relegated to an appendix. We welcome a practical handbook; it serves a very useful purpose because it gives to students precise directions about the use of the microscope, the staining and cultivation of microbes, and the identification of the living agents of infectious disease. The book which Professor Mackie and Dr. McCartney have written, though designed for the use of medical students, will certainly be useful also to more experienced laboratory workers because of its references to recent improvements in technique. The authors have handled difficult subjects very skilfully; questions not easily understood by the student, such as the magnification and numerical aperture of objectives, and the standardization of media by the hydrogen-ion concentration, are carefully explained. The book is of convenient size, well arranged, adequately indexed, and provided with a number of blank pages for notes at the end. It is likely to be a popular book with students.

Professor J. W. BIGGER's book is entitled a *Handbook of Bacteriology for Students and Practitioners of Medicine*.<sup>7</sup> It appears from the preface that Dr. Bigger's students have often complained that existing textbooks are too much encumbered with unessential matter, and the student does not find it easy to distinguish between the more important and the less. We believe that murmurs of discontent have been heard elsewhere than in Dublin. A medical student is happiest with a book which will tell him clearly all he needs to know in order to satisfy his examiner. He hates superfluity, and also despises "cram" books, to which, however, necessity may compel him to resort. Dr. Bigger has succeeded in writing a book of about four hundred pages which gives all a medical student is likely to be asked about bacteriology. We have looked through it carefully and do not find that anything of importance has been omitted. It is illustrated with five coloured plates and sixty-six figures. Medical students, in Ireland at any rate, will have to think of some new excuse if in the future they fail to pass the bacteriology examination.

*Principles of Bacteriology*<sup>8</sup> is the title of Dr. ARTHUR EISENBERG's textbook. It is a useful book for nurses or for those studying bacteriology who have not had a medical training. A special feature which must serve to recommend it to this class of reader is that all difficult technical

<sup>5</sup> *Insanity and Law: A Treatise on Forensic Psychiatry*. By H. Douglas Singer, M.D., M.R.C.P. Lond., and William O. Krohn, A.M., M.D., Ph.D. Philadelphia: P. Blakiston's Son and Co. 1924. (Demy 8vo, pp. xii + 437. 6 dollars.)

<sup>6</sup> *An Introduction to Practical Bacteriology, as Applied to Medicine and Public Health*. By T. J. Mackie, M.D. Glas., D.P.H. Oxford, and J. E. McCartney, M.D., D.Sc. Edin. Edinburgh: E. and S. Livingstone. 1925. (Cr. 8vo, pp. 297; illustrated. 8s. 6d. net.)

<sup>7</sup> *Handbook of Bacteriology for Students and Practitioners of Medicine*. By Joseph W. Bigger, M.D. Dublin, F.R.C.P.I., D.P.H. London: Baillière, Tindall and Cox. (Demy 8vo, pp. xv + 413; 66 figures, 5 plates. 12s. 6d. net.)

<sup>8</sup> *Principles of Bacteriology*. By Arthur A. Eisenberg, A.B., M.D. Third edition. London: Henry Kimpton. 1924. (Post 8vo, pp. 216; 40 figures. 10s. 6d. net.)

words are explained by giving a translation of the Greek or Latin from which the word is derived. In a short, semi-popular book of this sort the main difficulty is not what to put in, but what to leave out, and, on the whole, the author has been wise in his selection. The book would have been more accurately named "Principles of Medical Bacteriology," for it concerns itself entirely with pathogenic germs. It is true that it contains paragraphs on the bacteriology of air, water, soil, and milk, but very little space is given to these subjects, and the only germs to which the author refers are such as cause disease in man.

*Pathogenic Microorganisms: A Practical Manual for Students, Physicians, and Health Officers* is a popular American textbook of bacteriology written by Drs. WILLIAM PARK, ANNA WILLIAMS, and CHARLES KRUMWIEDE. It has grown with the times. The first edition was called *Bacteriology in Medicine and Surgery*, and the present title appeared first with the third edition. In the succeeding editions which have been called for new matter has been added and the old rewritten, so that the eighth edition now presented bears little resemblance to the original volume. It differs from its immediate predecessor chiefly in that alterations in nomenclature have been made in order to conform with the classification adopted by the Society of American Bacteriologists. It contains also a valuable section on experience gained in New York with active immunization against diphtheria, and it includes the new views which have recently been put forward on the etiology of scarlet fever, measles, typhus fever, and tularemia. This is a much more comprehensive book than either of the other three reviewed above. It contains over 800 pages and is illustrated with 211 engravings and 9 full-page plates. Its substantial proportions appear to be a product of American team work, for in addition to the three authors whose names appear on the title-page, those of three other doctors are mentioned in the preface, who, because of their specialized knowledge, have been asked to revise or rewrite particular chapters of the book.

### JACOBINE DIVAGATIONS.

To the far-flung many who were medical students at Edinburgh University within the past forty years the *Divagations of a Doctor*,<sup>10</sup> from the pen of Dr. ALEXANDER JAMES, will be very welcome. For all who know him are loyal "Jacobites": to them, while in "Auld Reekie," he was James I and Last; there was no room for any other James. "These divagations" (he says himself) "of a septuagenarian Æsculapian are dedicated to his brother Æsculapians present and future, obviously without their permission, but with his assurance that at any rate a perusal can do them no harm." This mildly negative claim upon the attention of his fellow club members is characteristically modest; for no one can read his book without being the better of it. Gifted as he is with the power—none too common—of writing both good English and good sense, and hating (as he honestly and openly does) all millennium-mongers, his papers on "The doctor in evolution," "Tubercular disease and germ," "The school teacher in evolution," "Juvenile crime," "Socialism in evolution," "State-made millenniumitis," and "Individual and communal evolution," are well worthy of being read and digested by all medical practitioners throughout the length and breadth of Great Britain; while "The Æsculapian oration on its 150th anniversary" is provocative of healthy chuckling. But whether it be prose or verse, he never "jokes w' deefenulty," and when one reads even in cold print his "Golfing song" or "Stop percussin', Jock," the kindest memories crop up of his inimitable singing of them, and the characteristic play of features and hands that drove the points home.

<sup>10</sup> *Pathogenic Microorganisms: A Practical Manual for Students, Physicians, and Health Officers*. By William Hallock Park, M.D., Anna Williams, M.D., and Charles Krumwiede, M.D. Eighth edition. Philadelphia and New York: Lee and Febiger; London: Baillière, Tindall and Cox. 1924. (Med. 8vo, pp. x + 811; 211 figures, 9 plates. 5s. net.)

<sup>11</sup> *Divagations of a Doctor*. Being a Commixture in Prose and Verse, Medical and Lay, Grave and Convivial, Social and Personal, Polite and Vulgar. By Alexander James, M.D. Edinburgh and London: Oliver and Boyd. 1924. (Fool 8vo, pp. 192. 4s. net.)

### NOTES ON BOOKS.

Dr. G. DELAMARE, who is professor at the Constantinople Faculty of Medicine, has devoted an interesting and richly documented monograph to the study of respiratory spirochaetosis.<sup>11</sup> The condition is defined by him as the series of nasal, laryngeal, tracheo-bronchial, alveolar, and pleural manifestations of a catarrhal, haemorrhagic, suppurative, febrile, or gangrenous type caused by the presence in the respiratory tract, and more rarely in the pleura, of a large number of spirochaetes which have been identified with *S. buccalis* (Cohn, 1875), *T. dentium* (Koch, 1877), *S. vincenti* (Blanchard, 1906), or *S. bronchialis* (Castellani, 1907). After an historical sketch, in which the author rightly attributes the first satisfactory description of the disease to Castellani, an account is given of its geographical distribution; it is shown that bronchial spirochaetosis, far from being exclusively a tropical disease, may be found in all latitudes in a sporadic form. The following sections deal with the etiology, parasitology, experimental pathology, epidemiology, morbid anatomy, symptomatology, diagnosis, prognosis, and treatment. It is noteworthy that arsenical preparations, which have such a rapid and striking effect in infections with Vincent's organisms, are often disappointing in bronchial spirochaetosis. A copious bibliography of recent literature is appended.

IN THE BRITISH MEDICAL JOURNAL of January 24th, 1925 (pp. 179-185), a very full report was given of the joint meeting of the Sections of Medicine and Electro-Therapeutics of the Royal Society of Medicine, held on January 16th, when a preliminary report on the electronic reactions of Abrams, with special reference to the galvanometer technique of Boyd, was presented by Sir Thomas Horder on behalf of a small investigating committee of which he acted as chairman. The other members were Dr. C. B. Heald, medical adviser to the Director of Civil Aviation; Lieut.-Colonel H. P. T. Lefroy, head of Wireless Research at the Air Ministry; Mr. W. Whately Smith, employed as a physicist at the same Ministry; and Mr. M. D. Hart, employed as a physicist at the War Office. The committee at a later stage had the co-operation of Mr. E. J. Dingwall, research officer to the Society of Psychological Research, and was assisted by Mr. H. St. G. Anson, recommended by the authorities of Faraday House for his ability to undertake original work in experimental physics. The full text of the committee's preliminary report has now been published in pamphlet form.<sup>12</sup> The report is arranged under the following headings: Foreword; introductory; historical and descriptive, the claims of Abrams; critical review of previous investigations and comments; the genesis of the present inquiry; the *prima facie* evidence; the nature of the problem; the first phase of the inquiry; the second phase, critical tests; conclusions; afterword. There are two appendices, one being a report by Mr. Whately Smith on galvanometer tests conducted with Dr. W. E. Boyd at Glasgow in June, 1924, and the other an account of a second series of experiments in Glasgow at the end of August.

A report of the lecture Professor René Cruchet of Bordeaux gave under the auspices of the University of London at the end of February was published in our issue of March 7th (p. 474), and we are indebted to Professor CRUCHET for a copy of a book entitled *Les États Parkinsoniens*<sup>13</sup> by himself and Professor VERGER, with the assistance of Dr. Anglado and Professor Hesnard. The general character of the valuable work done in the Bordeaux School of Medicine will have been gathered from Professor Cruchet's lecture. The volume consists of the text of eleven lectures delivered during the summer session last year; they were founded upon researches which were commenced in 1919.

*Medical Electricity for Nurses*,<sup>14</sup> by Dr. HAROLD WIGG, radiographer to the Royal Buckinghamshire Hospital, is a useful little handbook. Since, to-day, many small hospitals have well equipped electrical departments it is necessary that nurses should acquire a working knowledge of medical electricity. This education cannot be gained without some knowledge of the principles of electricity. Dr. Wigg supplies such information in simple and popular language. He describes also the different forms of apparatus used in electrical diagnosis and treatment. The book is well illustrated.

<sup>12</sup> *Electronic Reactions of Abrams*, with special reference to the galvanometer technique of Boyd. London: John Bale, S. post 8vo, pp. 55. 2s. 6d. net.)

<sup>13</sup> *Les États Parkinsoniens et le Syndrome Bradykinétique*. Par Henri Cruchet et René Cruchet. Paris: J. B. Baillière et Fils. 1925. (Demy 8vo, pp. 204; 24 figures.)

<sup>14</sup> *Medical Electricity for Nurses*. By Harold Wigg. London: Scientific Press, Ltd. 1925. (Cr. 8vo, pp. viii + 80. 3s. 6d. net.)

## PREPARATIONS AND APPLIANCES.

*Ethidol.*

The molecule of ricinoleic acid, the acid radicle of the principal constituent of castor oil having the ethylenic double bond, combines directly with iodine. The compound thus produced (iodo-ricinoleic acid) presents active iodine in true organic combination. In the form of a calcium salt it has been used with success in the treatment of goitre, rheumatoid arthritis, and some skin affections. The ethyl ester of the same compound is now being manufactured by Messrs. Burroughs Wellcome and Co. as an alternative to the calcium salt, and is sold under the name of ethidol. It is a liquid of oily character, but hardly to be called viscous; by virtue of its chemical constitution it is more easy of absorption than any corresponding compound derived from other fatty acids. It is suitable for intraglandular injection, and may also be used as an injection. It is not injured by heating to the temperature of boiling water for sterilization.

*An Electric Bed-warming Apparatus.*

The Medical Supply Association (167-185, Gray's Inn Road, London, W.C.1) has manufactured an electric apparatus for applying warmth to patients in bed. The apparatus consists of two shallow boxes in which are fitted electric lamps, which are covered on one surface with a wire guard, which prevents the patient coming in actual contact with the lamps. These boxes are placed right and left of the patient, and extend the whole length of the bed. They are held together at the bottom by a light bar.

## BRITISH EMPIRE EXHIBITION, 1925.

## MEDICAL SECTION.

With the commencement, in the first week in May, of the second year of the British Empire Exhibition at Wembley, there will be thrown open to the general public one of the most comprehensive and detailed displays of the steps in the evolution of modern medicine and hygiene that has yet been devised in any country. The Ministry of Health, which is responsible for the organization of this section, has received active support from a large number of public health authorities, museums, and commercial firms. It has set out to trace the story of medicine through past ages, to illustrate the present, and to anticipate the future, so that the various exhibits may appear as episodes in a drama rather than as curiosities on a museum shelf. Besides a large number of models of various kinds, and an extensive collection of objects of historical interest, there will be even more striking illuminated diagrams than those which characterized the Tropical Health Section in last year's Exhibition; summaries of the exhibits will be provided on the walls, so that visitors will have their attention drawn to the most important subjects illustrated. A small guide book to be published in connexion with this section will serve as a memento, and also have an educational value. That part of the British Government Pavilion which was devoted last year to the Navy, Army, and Air Force has been taken over this year by the Ministry of Health for its section, and the three halls will depict medicine in the past, the present, and the future.

*Medicine in the Past.*

On entering the Exhibition some primitive ideas of preventive medicine will be suggested by a life-size tableau of an African "medicine-man," from which the transition is natural to a collection of charms, votive offerings, and amulets, ranging from the prehistoric to rheumatism rings of the present day. It is perhaps significant that this part of the Exhibition is entitled "past-present," with the possible implication that there still remain vestiges of the ancient superstitions in some popular conceptions of disease to-day. The total contents of this section will be indicated by an illuminated kaleidoscopic apparatus, continuously calling attention in the space of a minute or so to the outstanding exhibits. Another life-size tableau will illustrate the days of the mediaeval alchemists, one of their "kitchens" being shown completely equipped with the actual crucibles and other apparatus in which the lotions and elixirs were compounded, and researches made in the transmutation of metals. This tableau will be balanced, so to speak, by another showing a modern

bacteriologist at work in his laboratory, and a public health chemist engaged in water analysis. The historical aspects of certain diseases, such as leprosy and malaria, will also receive consideration. In connexion with the latter disease there will be a complete exhibition of models of all the biting insects of England, in addition to the mosquito. Maps will show the extent of malaria in this country in the past and the present, and the stages of the evolution of quinine treatment will be demonstrated. In the case of leprosy the story of the preparation of the ethyl esters from chaulmoogra oil will be told. In one bay dealing with plague will be shown the various procedures adopted to prevent such diseases invading England; mooring cables with rat-guards attached, and the various other appliances used by port sanitary officers, will be represented. Special attention is paid to louse-borne diseases, such as typhus and relapsing fever; the improved disinfectors used in the war in various countries will be contrasted with the most modern achievements of bacteriology. A collection of old toilet requisites, dug up in the London area, and largely concerned with the care of the hair, will illustrate another side of the prevention of disease.

*Modern Medicine.*

In the hall devoted to modern medicine the first collection is concerned with infectious diseases, and an interesting group of allegorical paintings of such diseases as typhoid and plague has been brought together. The intention is to illustrate the importance of the control of these diseases by isolation, and secondly, the possibility of producing immunity in a certain number of cases. A model of the general lay-out of a modern fever hospital has been constructed, and the problems associated with small-pox and vaccination are also dealt with. Particular interest will doubtless be taken in what may be termed the "Lister exhibit," illustrating the conquest of sepsis. An illuminated model of the original ward in which Lister worked has been prepared, special attention being paid to perspective so as to introduce the atmosphere of reality, which is so often lacking in models of this kind. A collection of the instruments of this period with their wooden handles will indicate some of the advances that have been made in surgery in consequence of Lister's work. Several copies have been obtained of old paintings of operations in ancient days, and the surgery of those times will be further thrown into relief by the contrast provided by a full-size model of a modern operating theatre with all the most recent improvements. A novel and striking representation is being prepared to indicate the increasing possibility of utilizing products derived from the household refuse collected in town cleansing. Filtration and purification processes of water will be demonstrated, and a model will furnish striking illustration of the fly peril. In the centre of this hall there will be several working models illustrating modern methods of water purification and sewage disposal, including a complete lay-out of sewage disposal works. The water supply of Liverpool and other towns will be depicted by photographs, and some of the supply pipes of old London will also be shown.

*Medicine To-day and To-morrow.*

In the third part of the Exhibition the Ministry of Health will attempt to indicate the lines along which further progress in health is likely to run, as well as to illustrate the more recent improvements in the prevention and treatment of disease. Considerable attention will be devoted to maternity and child welfare; the model of a maternity ward has been prepared, and a considerable collection made of clothing worn by children at different historical periods. A comparison of the shoes of ancient times with those of the present will suggest that the modern rivalry between square and pointed toes is of very ancient origin; the evil effects of imperfectly fitting footwear will also be shown. Different varieties of children's feeding-bottles, including Roman and mediaeval types, will be displayed. The value of sunlight in respect of human growth and health will be illustrated by comparison with plant life. Dental problems will be represented by models of teeth, healthy and diseased; the need

of dental care in childhood will be graphically shown, and a series of tooth forceps used through the ages, including ancient Egyptian times, is presumably meant to convey a cautionary message. Progress in orthopaedics will be shown by various models, illustrations, and apparatus. The modern tendency to provide more open air for children in their educational hours finds expression; a model of an open-air classroom will be shown, and the way to secure more accommodation for open-air games will be indicated. Another section will be concerned with the training of mentally defective children in various grades, showing the great advance that has been made in this matter and the encouraging results that are being obtained. A further exhibit will illustrate propaganda work against venereal diseases, and the prevention and treatment of tuberculosis will receive, as is right, very considerable attention. The various possibilities of sunlight treatment will be demonstrated, and a model will be shown of a sunlight treatment centre, together with the provision of artificial sunlight by means of ultra-violet ray lamps. Other illustrative models in this connexion will include the general layout of a sanatorium, revolving shelters, and sanatorium wards.

The smoke prevention exhibits of the last exhibition will be extended to teach the deleterious effect of coal smoke, not only in disintegrating stonework, but also in cutting off rays of light from human beings. Improvements in town planning will be shown by models of good and bad plans; also diagrammatic representations of slum areas that have been abolished, and of good and bad principles in house construction generally. It may here be mentioned that the Minister of Health is chairman of a committee which is arranging a great housing display occupying over 60,000 square feet in the Palace of Engineering. Besides illustrating various types of working-class houses, week-end cottages, and bungalows, this will include sections of walls and component parts to demonstrate improvements in construction designed to make these houses far healthier than those of the past. In a section dealing with trade diseases, attention will be paid to diseases notifiable under the Factories Act; one exhibit illustrates how infection was spread by "shuttle-kissing" under old conditions, and how these shuttles have now been replaced by others in which there is no possibility of the thread being sucked through by the workers. Gas poisoning in factories and mines will be dealt with, and the apparatus used in prevention and rescue work will be shown. The food models will probably cause general interest: an attempt will be made to indicate what people should eat at various ages, and model diets for different meals will be realistically displayed. Other models and exhibits will be devoted to vitamins, the production of pure milk, clean meat, and the present thorny problems of food preservation.

### CEREAL FOODS AS A FACTOR IN RICKETS.

THE Medical Research Council has just issued a report by Professor Edward Mellanby on the effect of cereals and their interaction with other factors of diet and environment in producing rickets,<sup>1</sup> in which he describes experiments made with the object of developing this aspect of the problem of rickets. As he observes in his introduction, probably in no physiological activity so far studied do action and reaction of dietetic elements stand out more prominently than in the growth and hardening of bone.

This research proves that the various common cereals—oatmeal, wholemeal flour, white flour, rice, barley, etc.—have different effects on the growing animal, and that such differences cannot as yet be explained on the basis of their known constituents. Evidence is brought forward showing that some cereals and cereal products have a strongly adverse influence on bone calcification, and that this varies, not only with the amount and type of the particular cereal eaten, but with the general make-up of the diet. The "cereal action" can be completely antagonized by the

antirachitic vitamin, especially by cod-liver oil, and to some extent also by exposing either the animal or the cereal food to ultra-violet radiations.

Many of the experimental results detailed in the present report have already been described by the author when making communications to various scientific bodies; for example, in the Oliver-Sharpey Lectures before the Royal College of Physicians in 1922, and in his paper read to a joint meeting of the Sections of Physiology and Diseases of Children at the Glasgow meeting of the British Medical Association in the same year, when opening a discussion on the etiology of rickets.<sup>2</sup> Since then he has endeavoured to follow the sequence of events, and more especially to find the substance or substances in cereals which under some conditions interfere with the calcification of bone and the proper functioning of other tissues. The task, he says, has proved more difficult than he supposed, for its solution does not appear to depend, as seemed at first likely, upon some well recognized dietetic factor or factors. Although the research is still incomplete, he reports progress at the present stage for three reasons. One is the practical importance in dietetics of the facts so far observed; the second is because they put into better perspective the significance of the phosphorus and calcium elements of the diet in the etiology of rickets; the third is the emphasis they give to the great importance of balance in dietary constituents. On this last point he writes of the "constant battle going on among dietetic elements as regards the calcification of bone, some substances stimulating and others preventing the process; and the ultimate structure of the bone is the outcome of the conflict."

Most of the experiments here recorded were carried out at the Field Laboratory, Sheffield University, in which the conditions were more uniform than those at Cambridge, where much of the earlier work was done. Professor Mellanby first gives an account of experiments demonstrating the relative rickets-producing effect of different cereals, and then describes some of the attempts made to discover the cause of these differences. Later, he marshals the evidence showing that this cereal effect can be modified in varying degree, not only by other constituents of the diet, but also by ultra-violet radiations.

With a diet deficient in antirachitic vitamin, increasing the amount of cereal brings about worse-formed bones if other factors of diet and environment remain constant. Of the different cereals examined, oatmeal, contrary to what might be supposed, has by far the worst influence on bone formation. Next come maize and barley, rice, and wheaten flour, the last having the least harmful effect. The germ of wheaten flour, if enough is added, also interferes with bone calcification.

Of the foodstuffs containing the antirachitic vitamin which antagonizes "cereal action," cod-liver oil is by far the most effective, and quite small quantities suffice. Whole milk in fairly large amount, and egg yolk, are also potent antagonists; but butter, unless accompanied by a fairly high calcium intake, is of comparatively small value. Both calcium carbonate and calcium phosphate work well in conjunction with the vitamin of butter fat. The antirachitic effect of separated milk is more potent than can be accounted for by its calcium content alone. Even when the diet is greatly deficient in antirachitic vitamin the development of rickets is hindered to some extent by increasing the calcium content, preferably by addition of the carbonate.

As regards the means whereby cereals bring about this rickets-producing effect, Professor Mellanby suggests that two different kinds of action may be at work:

"In the first place that part of the cereal which is actually incorporated in the growing organism and leads to its growth is probably partially responsible. In this way the carbohydrate and the protein would be involved. In the second place there is present in the one cereal tested—namely, oatmeal—a chemical grouping which, after digestion and absorption of the grain, is capable of interfering with bone calcification. After many attempts had been made to explain this action in terms of known constituents of cereals and to find out the nature of the causative agent or agents, some evidence has finally been obtained which suggests that a substance in oatmeal which interferes with the laying down

<sup>1</sup> Experimental Rickets. Special Report Series, No. 33. London: H.M. Stationery Office, 1925. (2s. 6d. net.)

APRIL 11, 1925]

## NOVA ET VETERA: WILLIAM LEVETT.

of calcium in bones is associated with the fatty acids. This substance can be obtained by saponification of oatmeal with soda and extracting the acidified mixture with petrol ether. Further work is necessary to establish the nature and properties of this cereal constituent and also to determine its mode of action."

A little further on in the summary of results he writes:

"Since the antirachitic vitamin supplies in the food and exposure of the animal or of the food eaten to ultra-violet radiations tend to conserve ingested calcium and phosphorus for the use of the growing organism, and since the cereals work in the opposite direction, it is evident that the amount of calcium and phosphorus in the food is of but secondary importance in the control of the deposition of these elements in growing bone, although, of course, there must be a sufficiency of these salts for the formation of perfect bones. In view of the evidence of interaction and balance among food constituents provided by this investigation, the value of the expression 'optimum calcium content of a diet,' so commonly used in dietetic descriptions and discussions nowadays, must be doubted. The optimum varies every time the other elements of the diet are changed."

In conclusion, Professor Mellanby touches briefly on two practical points of dietetics which arise out of the experimental findings set out in this report. One is the question, Why, if oatmeal is so detrimental to bone formation, fine races of men have been reared on diets of which this cereal forms a large part? The other is, What is the bearing of these experiments upon the wholemeal versus white bread controversy? In answer to the first question, the author suggests that the diet of the oatmeal-eating people has also included much of foods rich in antirachitic vitamin (milk, eggs, and fat fish); while in tropical countries, where cereals such as rice and maize form a large part of the diet, the sunlight is no doubt an important factor in antagonizing the work here recorded shows that perfect bone formation can be obtained even when large quantities of oatmeal are eaten, provided the rest of the diet is adequate. In regard to the controversy about wholemeal bread and the nutritive properties of the wheat embryo, Professor Mellanby thinks this question is of but little practical importance from the point of view of rickets. To those who ascribe special virtues to various grains because of their calcium and phosphorus content, his experimental results, he suggests, ought to bring a special message of caution.

## Nova et Vetera.

## WILLIAM LEVETT.

On January 17th, 1782, Dr. Johnson wrote, "Our old friend, Mr. Levett, who was last night eminently cheerful, died this morning," adding, "so has ended the long life of a very blameless and a very useful man." Thus did Johnson epitomize the character of his apothecary comrade, William Levett, whom he had befriended for close on forty years, and who for a long period of time had been one of the inmates of the lexicographer's home, "where Mr. Levett occupied his post in the garret," says Boswell. The occasional references to Levett in Boswell's *Life of Samuel Johnson*, and an article in the *Gentleman's Magazine* for February, 1785, give indications from which interest may be gleaned, and an endeavour made to reconstruct his story and character.

Levett was originally a waiter in a Parisian coffee house, which was a resort of the medical fraternity. These patrons, noting his aptitude, made a subscription and themselves gave him tuition, arranged for his admission to lectures, and so started him on his professional career. Later we find him in practice in London, apparently in the neighbourhood of Fleet Street. It is obvious that his clientele was of the humblest: Boswell calls him, with perhaps a touch of scorn, "an obscure practitioner of physic amongst the lower people," but also states that his practice was so widespread that he used to walk from Houndsditch to Marylebone. His fees were small, and where money was lacking he was sometimes content to be paid in provisions, and sometimes, it is to be feared, in less reputable ways. Johnson says that Levett was probably the only man who ever became intoxicated through motives

of prudence: the interpretation of which cryptic saying is that, as there might be no other reward, would take what he, being apprehensive of no other reward, would take what was offered at the moment in the guise of gin or brandy. Perhaps it was this unusual form of prudence which limited his clientele, perhaps also his manner and appearance, for we are told that he was "of a strange grotesque appearance, stiff and formal in his manner," and that he possessed a "visage swarthy, adust, and corrugated." But whatever others may have thought of Levett, Johnson had a high opinion of him; indeed, he told Boswell that unless he had Levett with him also he would not be satisfied with the presence of the whole College of Physicians. Levett's attendance on the sage appears to have been generally fortified by the advice in earlier days of Dr. Lawrence, and later of Dr. Heberden.

Besides being handicapped by an ungainly mien and a corrugated visage and the nature of his fees, poor Levett contracted an unfortunate marriage. Johnson says in one of his letters, "Levett is lately married not without much suspicion that he has been wretchedly treated in his match," and again, "Mr. Levett has married a street walker." There was certainly ground for suspicion. The lady cozened her suitor with the story that she was a member of a wealthy family, and on the other hand was led to entertain the view that he was a prosperous physician. There was rapid disillusionment, and Mrs. Levett was soon afterwards arrested for pocket picking. It was said rather unkindly that Levett was with difficulty dissuaded from attending the trial in the hope that she would be sentenced to death. She was, however, acquitted, and the ill matched pair then parted.

It appears to have been at this juncture that Johnson, with his warm-hearted practical sympathy, made his friend a member of his household; as Goldsmith put it, that he was poor and honest was sufficient recommendation to Johnson. Here he lived for the remainder of his life, though seemingly not in complete amity with the other inmates—"Levett hates Desmoulins and does not love Williams." He was not a dependant, for Johnson says that Levett was never indebted to him save for his share in a penny loaf at breakfast and an occasional Sunday dinner. At this breakfast table Levett would preside over the tea kettle, and a visitor says that Johnson would tear out the crumb of bread for himself and throw over the crust to his housemate. After breakfast the obscure practitioner would leave the house and was generally not seen again until midnight; doubtless if his daily round involved a tramp from Houndsditch to Marylebone his hours would need to be long, and he it said to his credit that some of his time was spent in attendance on Hunter's lectures.

Such is a brief summary of Levett's career until his sudden death and his burial in St. Bride's. He makes an enigmatic figure as he flits across the interesting stage of that period: a lean, swarthy, ungainly man, the friend and companion of one of England's greatest men, privileged to see and to converse with others whose names are writ large, but spending his working days in a weary round of ill requited toil beside the sick beds of the poor. It was the curiously assorted career of a curiously assorted man. Johnson, with his accustomed charity, enshrined the virtue and excused the weakness, and so Levett was to him a very good and a very blameless man. And he filled in the picture with generous lines in verses which he later wrote, of which these may be quoted:

In Misery's darkest cavern known,  
His ready help was ever nigh,  
Where hopeless Anguish pour'd his groans,  
And lonely Want retir'd to die.

No summons marked by chill delay,  
No petty gains disdain'd by pride;  
The modest wants of every day  
The toil of every day supply'd.

His virtues walked their narrow round  
Nor made a pause, or left a void;  
And sure the Eternal Master found  
His simple talent well employ'd.

So we say good-bye to Levett, "of every friendless name the friend," and fortunate himself in being befriended by the large-hearted Johnson and so remembered to-day.

## OSTEOPATHY AND CHIROPRACTIC.

In an article on osteopathy and chiropractic which we published on May 31st, 1924 (p. 963), the doctrines and methods of the two cults were fully examined, and it was pointed out that they exhibited no essential differences, the cults being, in fact, branches of one and the same stock. A notable difference, however, was indicated as regards their power of development. While each started on an equal level of ignorance, chiropractic remained stationary, whereas osteopathy exhibited a tendency to become assimilated to orthodox medicine by the introduction of such subjects as bacteriology and surgery into its curriculum. This being so, it was inevitable that the interests of the two cults should ultimately come into collision, the chiropractors enjoying an undue advantage over their osteopathic competitors because their system requires no medical knowledge or technical skill. Matters appear now to have reached an acute stage in this respect, and osteopathy as a back entrance to medical practice is ceasing to be attractive in comparison with the cheaper introduction afforded by chiropractic.

In these circumstances it is not surprising that osteopaths are seeking to strengthen their position, and they have, accordingly, called in aid the services of members of Parliament. A circular, signed by twenty-one members, was recently issued to M.P.s inviting them to attend a meeting of the British Osteopathic Association to hear an address by Dr. W. Kelman Macdonald of Edinburgh on the present position of osteopathy. The meeting was held on March 31st, about thirty members of Parliament attending, and a report of the proceedings will be found at page 716. Dr. K. Macdonald, after giving an account of the principles and methods of osteopathy, urged, first, that the Legislature should grant the British Osteopathic Association the privilege of conferring diplomas in osteopathy; and, secondly, that the General Medical Council should be debarred from forbidding anaesthetists to work with registered osteopaths.<sup>1</sup> The resolution of the General Medical Council will be generally regarded as a wise one, but were Parliament to see fit to authorize the conferring of diplomas in osteopathy the rule might then, apparently, be held not to apply to those holding that diploma. The question of interest, therefore, is reduced to that of the desirability or otherwise of granting diplomas in osteopathy.

A canvass of the medical profession on this matter would probably disclose an almost unanimous opposition to the granting of such a diploma, but some members of Parliament, in common with other laymen, may find a difficulty in arriving at an independent opinion, owing to the tendency for the issues involved to be obscured by technicalities. Divested of technicalities, however, the problem should not be difficult of comprehension. If existing recognized

<sup>1</sup> *Forming Notice of the General Medical Council:* "5. Association with unqualified persons.—Any registered medical practitioner who, either by administering anaesthetics or otherwise, assists an unqualified or unregistered person to attend, treat, or perform an operation upon any other person, in respect of matters requiring professional discretion or skill, will be liable on proof of the facts to have his name erased from the Medical Register."

diplomas are examined it will be found that the differ from one another, not in respect of medical tenets or doctrines, but as regards the extent of the responsibility to be assumed. The diploma in dentistry places

practitioner in all diseases relating to the teeth, excluding him from taking responsibility in more general diseases, such as typhoid fever, which, if they came under his notice, he would properly hand over to the physician. A registrable diploma in medicine, on the other hand, has the widest possible scope, and permits the assumption of responsibility in disease of every kind, although it is customary for the practitioner to call in the assistance of the dentist in cases that fall within his proper sphere. In practice, however, the distinction is not as clean-cut as it might at first appear. Patients suffering from disorders which fall strictly within the province of the medical practitioner may, in the first place, apply for treatment to the dentist, and it therefore behoves the latter to have some knowledge of medicine generally, in order that he may avoid the danger of failing to recognize the disease and that he may transfer the patient to the proper quarter. The ideal arrangement is that adopted in this country, as also in France, Germany, and the Scandinavian countries—namely, that all medical practitioners must be qualified to practise medicine, surgery, and midwifery. The Medical Act of 1886 laid down in effect that no one might have his name entered on the *Medical Register* unless he had passed a qualifying examination in all three branches. Turning now to the osteopaths, we find that they undertake responsibility for treatment in disease of every kind, although, like regular medical practitioners, they hand over certain cases to the surgeon. It is obvious, therefore, that the type of diploma appropriate to them is the medical diploma and nothing less. The existing diploma is available, and they should take it before receiving a licence to practise. According to a manifesto recently issued by the British Osteopathic Association the demand is for a more restricted diploma, corresponding to that in dentistry. The above considerations will show that such a demand is inadmissible; osteopaths deal with all manner of diseases, and therefore the wider medical diploma should be insisted on.

Assuming that the osteopath is willing to take a medical diploma, it remains to consider whether it is desirable to create a special diploma in osteopathy for him, to be taken in addition to the former. One reason put forward by Dr. K. Macdonald for demanding a special diploma is that if osteopaths become absorbed into the medical profession their discovery (if discovery it be) will be smothered. They desire to have another fifty years outside the profession in order to demonstrate their art. As we have pointed out above, diplomas have nothing to do with medical discoveries, but merely with the delimitation of medical responsibility. But apart from this, a mere glance into current medical literature will convince anyone that Dr. K. Macdonald's apprehensions are entirely unfounded. At the present day every claim to discovery that is properly advanced is criticized and canvassed all the world over; and such a striking "discovery" as that of the osteopaths—that almost all diseases under the sun have their one and only cause in slight irregularities of the backbone, and may in most cases be readily cured by a simple manipulation of the back—is not likely to be overlooked. Another reason given for the demand is that osteopaths have many impostors among them, and a recognized diploma would serve to distinguish the sheep from the goats.

Dr. K. Macdonald reports that impostors of this type are establishing schools in the Midlands at the present time, and expresses a praiseworthy desire that the public should be protected against them; but there is no need to create a special diploma for this purpose; the ordinary diplomas are available. On the whole, therefore, it appears that the osteopaths wish to join us and yet remain distinct. What is the object of this attitude? We can only surmise that they would find the proposed diploma useful as a species of trade-mark or advertisement. But that is not at all in accordance with the sentiments and traditions of the medical profession, and we bar it as inadmissible.

It may remove some misapprehension if an explanation is given of the manifest indifference with which osteopathy is received in this country on the part of medical men. It may, perhaps, be inferred that we consider there is nothing in it. Such is by no means the case. We are aware that osteopaths profess to make use of approved hygienic measures in their treatment, and that they attach importance, with a view to treatment, to deformities of the spine, such as lateral curvature, with which the regular practitioner is quite familiar. When, however, osteopaths refer innumerable diseases to small derangements in the form of the backbone—irregularities which we are unable to detect at *post-mortem* examination, with the body open before us—we regard their theories as far-fetched and fanciful, and, when applied to grave diseases such as typhoid fever and diphtheria, as decidedly dangerous. When we are asked to believe that a cold in the head, a crop of pimples on the face, an attack of vomiting and diarrhoea after a gorge, an attack of gout or measles—that these and a host of other diseases too numerous to mention are, one and all, due to small spinal irregularities which may be readily corrected by manipulation of the back, we experience a difficulty; it leaves us, so to speak, cold. It may be objected that no such difficulty has been felt in America, where osteopathy has had an enthusiastic reception. It should be remembered, however, that America is the land of freedom—freedom for faddists, among others. Just as, in the words of Dr. K. Macdonald, “the backbone is the happy hunting ground of the osteopath,” so America may be said to be the happy hunting ground of the crank. His activities have free play there, and, if need be, he will found a college to promulgate his notions. Few Englishmen realize the ease with which a State charter for an educational institution can be obtained in the United States, and the editor of *Truth* hardly exaggerated in saying that it seemed easier to establish a university in the United States than to open a “pub” in England. It was and is. Only ten of the forty-eight States in the Union make any provision for the slightest control over the charters of educational institutions. In thirty-eight States, therefore, any coterie of men, by paying an insignificantly small fee, can obtain permission to open an institution with the avowed purpose of granting any degree in any subject. When these States grant charters they ask no questions as to whether the institution is properly equipped or has teachers qualified to furnish the education usually demanded before degrees are granted. Furthermore, even after such institutions have been exposed as worthless or fraudulent there is no legal provision for revoking their charters. We are not to be understood as implying that osteopathic schools are necessarily fraudulent; our object is to point out that because in America a given State grants a charter to an osteopathic college, it does not follow

that such a college has any standing from an educational point of view. The conditions are not the same in the two countries, and we think that our osteopathic visitors will have to fall in with our ways.

## PULMONARY FIBROSIS.

UNDER the name “pulmonary fibrosis” are grouped together all chronic diseases of the lung which are characterized by an overgrowth of connective tissue. The fibroblastic cells, starting from situations where normally connective tissue is most abundant—that is to say, round air passages and blood vessels and interlobular septa—grow in all directions, compressing the air vesicles, causing the lung to lose its elasticity, and finally converting it into a tough, almost rigid organ. Such progressive degenerations betray themselves in many chronic diseases—in phthisis, for instance, or syphilis—but there are two causes of fibrous tissue overgrowth in the lungs of patients whose other organs are healthy: these are the toxic action of bacterial poisons and the inhalation of irritating dust. To these Sir Thomas Oliver may perhaps add a third if the experiments, described in his paper published this week (p. 685), on the intravenous injection of aluminium metal, bauxite, in a finely powdered state, should lead to pulmonary fibrosis, as his preliminary results suggest. In undertaking this line of research he followed the method of Dr. Drinker, who injected minute particles of manganese silicate intravenously and found structural alterations in the lungs of the injected animals. The argument seems to be that finely particulate material in the blood stream, when passing through the pulmonary capillaries, is taken up by the endothelial cells, and, once localized, may initiate a fibrotic reaction round about.

Returning to the two well established causes of fibrosis: The variety which appears after an acute lobar pneumonia is fortunately an unusual sequel, but a patchy type of fibrosis often attends the healing of bronchopneumonia, and, as Dr. Bernard Shaw and others have recently reminded us, a disabling overgrowth of fibrous tissue not uncommonly follows in the wake of influenza. Further discussion of these toxic origins of pulmonary fibrosis would take us too far from the main theme of Sir Thomas Oliver's lecture—occupational pulmonary fibrosis, a subject he has studied for many years. There are points in his paper which deserve special emphasis at the present time.

So much has been said about silicosis as a predisposing cause of tuberculosis that it is easy to overlook the fact that the serious deformity, silicotic pulmonary fibrosis, may be responsible for dyspnoea and marked reduction of respiratory capacity, in the absence of the more serious infection of the tubercle bacillus. Pulmonary silicosis is a disease *sui generis*: some cases may proceed to a fatal end without the lungs ever becoming tuberculous; this has been proved by the results of *post-mortem* examination. Patients with uncomplicated silicosis suffer from dyspnoea, and later, owing to obstruction of the circulation, from hypertrophy of the right heart, general venous congestion, and oedema. Undoubtedly many more victims of silicosis are hurried on the downward path by a superimposed tuberculous infection to which they are peculiarly susceptible.

Though all inhaled particulate matter is liable to damage the lungs, two factors—the shape and the size of the particles—determine the amount of damage which will be inflicted. The chemical composition also probably plays a greater part than has previously

been admitted. It would seem natural to assume that sharp mineral particles are more dangerous than smooth, and in support of this it is sufficient to mention the heavy toll of health demanded by rock drilling in the mines of the Transvaal. But damage follows the inhalation of particles other than the sharp and gritty, as witness the fibrosis of the lungs due to the inhalation of asbestos dust about which Dr. W. E. Cooke of Wigan wrote recently in this JOURNAL.<sup>1</sup> When the asbestos rock is crushed much fine dust and fibre escape into the workroom, and Sir Thomas Oliver describes how during these processes the atmosphere of the workroom is quite cloudy, so that the hair and clothing of the men become covered with white fluff. Asbestos contains a large quantity of silica compounds, and it is possible that this notoriously dangerous substance may be the chief agent in damaging the lung. A good deal of new work has been published lately on the mode of action of silica on the lungs, and it seems likely that the chemical composition and not the physical properties of silica dust is most to blame.

The second factor of chief importance is the size of the particles. The experiments which have been carried out by Dr. Mavrogordato in South Africa<sup>2</sup> teach us that particles above 10 microns in size are not very harmful to the lungs, and ultramicroscopic particles, less than a tenth of a micron in diameter, probably are not injurious at all. Curiously enough, it is the particles about the size of the common pathogenic microbes, 1 to 4 microns, which do most harm.

The health of the industrial worker is a problem of great national importance. In many industries employers now realize that the most hopeful path to increased production is improved health of the workers, for sickness is responsible for a tragic loss of time and efficiency. On the other hand, social statisticians tell us that restlessness and discontent among employees waxes and wanes with the tide of sickness. A healthy worker is more likely to be a contented worker; but sickness breeds ill will. Therefore, those who study occupational diseases and further our knowledge of how these may be diminished render a national service singularly helpful in these days.

#### DANGERS OF ULTRA-VIOLET LIGHT BATHS.

No one who has made himself acquainted with the benefits to be derived from ultra-violet light as a therapeutic agent can fail to recognize its value in certain forms of disease. That it can be followed by harm is less generally known, and it is therefore opportune that Sir Lenthal Cheatle has communicated in a letter (BRITISH MEDICAL JOURNAL, March 28th, p. 631) the result of some observations made by him on the skin of an individual "bronzed" by sunlight. The comments (April 4th, p. 679) of Dr. Leonard Hill on this letter seem to show that no real apprehension need be entertained as to the possibility of a late development of carcinoma among patients treated by this new remedy, and this is satisfactory so far as it goes. What, however, may appear to be disquieting is the use to which ultra-violet light is being put by those who possess little knowledge of its qualities. In a letter published in the present issue (p. 717) Dr. C. B. Heald states that a firm of builders contemplated equipping the bathrooms of some houses with ultra-violet lamps. If it were the case that the light generated by artificial means were exactly similar to sunlight, no doubt only good would result; but as it is well known that in certain circumstances exposure may be followed by most undesirable results the procedure would appear to be of very dubious value. We know that the

eyes have to be carefully protected, that persons of a light complexion may be considerably affected, that in cases of pulmonary tuberculosis the disease may be aggravated, and that other, if minor, inconveniences may be caused. Dr. MacCormac and Dr. McCrea record in this issue (p. 693) the very serious consequences that followed an unduly prolonged exposure in a patient who was taking "light baths" without medical advice. Where this remedy is used, as it should be, under proper control, it is a powerful agent for good. The public have come to believe that ultra-violet light in all forms can be employed with perfect safety, a belief that has already been productive of harm. It would be well if they were to recognize that overdosage may occur, and may be attended with unexpected and undesired consequences.

#### QUEEN MARY'S HOSPITAL AT ROEHAMPTON.

In our issue of August 11th, 1923, we announced the decision of the Minister of Pensions to transfer the Special Surgical Hospital from Du Cano Road, Shepherd's Bush, to Roehampton House. This change was made necessary by the decision of the Hammersmith Board of Guardians to resume possession of the premises at Shepherd's Bush, which had been built and used as a Poor Law infirmary previous to their lease to the Government during the war. Queen Mary's Convalescent Auxiliary Hospital at Roehampton was established in 1915 in order to supply prostheses to the large number of officers and men who had lost limbs in the war; there they were dealt with in ever-increasing numbers until at one time there were nearly 1,000 patients in hospital at a time, and over 300 first limbs were supplied every month. This was rendered possible by supplementing the accommodation in the old house and its wings by wooden huts. Unfortunately the committee did not see fit to make any provision for the performance of operations, and consequently those patients—and they were many—whose stumps required active surgical treatment had to be transferred temporarily to other institutions. An artificial separation was thus made between operative and prosthetic orthopaedic surgery, and this separation became still more marked when the Military Orthopaedic Hospitals (since renamed Special Surgical Hospitals) were established under Sir Robert Jones. The intention referred to by us in August, 1923, is now being carried into effect, and on May 6th the necessary extensions at Roehampton will be formally opened by the Queen, who has always taken a warm interest in this hospital and those associated with it. These extensions consist of five new wards built of brick, each containing forty beds, which have replaced some of the wooden huts, an operation block containing two theatres, and special wards for electrotherapeutics and other purposes. Five hundred orthopaedic and a few medical cases are being transferred from Shepherd's Bush this month, and eighty facial cases from Sidcup will follow. This reinforcement of Queen Mary's Hospital by the staff and patients from Shepherd's Bush will not affect the prosthetic work which is still being carried on in the limb-fitting hospital, for which there is still plenty of scope. In the last two years 500 limbs, which surgeons have been trying in vain to save, have been amputated, and the patients sent to Roehampton for the provision of artificial limbs. Moreover, there is a constant stream of old patients returning for the provision of new prostheses or the repair of old ones, to the extent of some eighty each week. The committee of Queen Mary's Convalescent Auxiliary Hospitals provides the buildings and maintenance for all the patients, but the surgical staff is appointed and paid by the Ministry of Pensions. The separation between prosthetics and orthopaedic treatment should never have occurred and has continued too long; but "all's well that ends well," and we heartily welcome

<sup>1</sup> BRITISH MEDICAL JOURNAL, July 26th, 1924.  
<sup>2</sup> *Ibid.*, March 21st, 1925, p. 566.

their reunion on the pleasant lawns and under the stately oaks of Roehampton House. The committee has long had in view the desirability of placing the skill and experience of the limb-makers at Roehampton at the service of civilian amputees. Arrangements have already been made with the great railway companies, the L.M.S. and the L.N.E.R., whereby all amputation cases among men in their employ may be sent to Queen Mary's Hospital for fitting. It is hoped that the colliery owners will soon follow suit, and no doubt further developments will occur, provided the cost of the prostheses supplied is within the means of charitable agencies which are without access to the public purse.

#### PENSIONS OF R.A.M.C. OFFICERS.

IN a leading article in the *JOURNAL* of October 18th, 1919, we called attention to the unfair manner in which majors in the Royal Army Medical Corps had been treated in regard to pensions under the new Royal Warrant. The much heralded increases that were to be given all round ended in these officers losing a sum of £44 per annum. Prior to the new Warrant of 1919 a major with twenty years' service was entitled to a pension of £1 a day, or £365 a year, and there is no doubt that to many officers this was a great inducement to join the service. Under the new order of things the pension of a major with twenty years' service was reduced to £321 per annum. We assume that this was an unforeseen result of the new method of calculating pensions—namely, the granting of a "service element" (in this case £225) and a "rank element" (£96). The Council of the British Medical Association at once called the attention of the War Office to two facts: first, that in this new pension scheme no financial recognition was being given to the R.A.M.C. officer for coming into the army fully equipped with his profession some five years later than officers in other branches whose professional equipment was obtained at the expense of the country; and secondly, that the major R.A.M.C. had actually lost £44 per annum on his pre-war rate of pension. The first matter was promptly dealt with in the following way. The sum of £75 was added to the "service element" for all medical officers, thus bringing the pension up to £300 from £225. The second matter has never been put right, because the "rank element" remained unaltered. The result of the addition of £75 was that the major got back the £44 he had lost, but only gained on the whole transaction £31, bringing his pension to £396—an increase of 8½ per cent. to meet an increase in the cost of living which at the time when the Warrant came out was 174 per cent. above the normal. Another extraordinary provision was that the new rate of pension was liable to a reduction amounting in all to 20 per cent., which was to be carried out by instalments—the first at the end of five years, and three others at the end of further periods of three years each. The inequity of this arrangement is now becoming apparent, because majors who were captains when the new Warrant came into force are just beginning to come due for retirement after twenty years' service. These officers, although they were in the corps before the new Warrant became effective, are given no option but to accept its terms. It is also worthy of note that whereas a soldier can retire on any warrant which gives him the most favourable terms, an officer cannot do so. A major with twenty years' service retiring to-day gets a pension of £396, less 5½ per cent. (approximately £20), leaving him with £375 as against £365 pre-war. A second reduction falls due three years from last July, and if this reduction is one of only 3 per cent. the whole of the increase over pre-war rates will have gone. As there is a provision for further decreases after the first, amounting in all to 14½ per cent., it is clear that, notwithstanding statements

which have been made to the contrary, the pensions of these officers can fall, not only below, but far below, the pre-war rate. They might, as a matter of fact, be reduced to about £320 per annum. This is bad enough, but the lot of the major who has counted twenty years by virtue of putting in service in certain unhealthy districts, where one year counts for two, is infinitely worse. The following case has just been brought to the notice of the British Medical Association, and we understand that there will be many more officers in a similar plight. X, who put in four years in an unhealthy climate, where time counts double for pension purposes (that is, eight years in his case), recently retired under the twenty years' provision after sixteen years' actual service, only four of which could be in the rank of major. His pension, therefore, under the present Warrant, worked out at £348—£300 service element and £12 for each year in the rank of major; but as the first reduction of 5½ per cent. had come into force before he retired he gets no more than £328, and in the next nine years his pension may be reduced to £280 because there is still a further 14½ per cent. reduction which can operate against him. He states that his chief inducement to join the corps was the fact that he would get a pension of £365 after twenty years' service or the equivalent of twenty years' service if he had served part of his time in unhealthy areas. These anomalies are due to the unfair operation of the rank element method of reckoning pensions, and also to the extraordinary provision that the increases given by the new Warrant are subject to a reduction of 20 per cent., not on the increase alone, but on the whole pension.

#### SIR THOMAS LEGGE.

SIR THOMAS LEGGE, the principal medical inspector of factories, who recently received the honour of knighthood, was entertained to dinner by his fellow workers in the sphere of industrial medicine at the Hotel Cecil, London, on April 1st. The arrangements had been carried out by the Association of Certifying Factory Surgeons, and its president, Dr. R. Prosser White, himself a well known authority on industrial skin affections, was in the chair. Certifying surgeons, experts in industrial medicine, representatives of the Home Office, medical and other members of Parliament, forgathered to the number of seventy. The guest of the evening was the recipient of many good wishes from far and near. Dr. Edsall of Harvard, Boston, cabled for himself and American colleagues, Dr. Glibert on behalf of the Belgian factory medical service, and Dr. Geier of Cincinnati for the U.S.A. Public Health Service. Of the numerous letters of felicitation received the most notable were from Sir Arthur Whitelegge, Professor Leonard Hill, Dr. C. S. Myers, Dr. H. M. Vernon, Professor E. Collis, Dr. J. C. Bridge, Dr. L. Carozzi of the International Labour Office, Geneva, and Mr. Rhys Davies, late Under Secretary of State. Dr. René Sand, secretary of the International League of Red Cross Societies, was at the last moment prevented from attending owing to the severe illness of a near relative. The President proposed the toast of the evening, and was followed by Sir Kenneth Goadby, who spoke as a very old friend and one of the earliest co-operators with Sir Thomas in his particular specialty. Sir Thomas Legge, in his response, gave a survey of the wonderful progress made by industrial medicine during the present century, and spoke very feelingly of the happy relationship which existed between himself and certifying factory surgeons. The toast of "Industrial medicine," coupled with the names of Sir Thomas Oliver, Dr. O'Donovan, and Dr. A. Leitch, was proposed by Dr. D. McKail. The visitors were toasted by Dr. T. Watts, M.P., and Mr. Bannatyne of the Home Office, Sir Gerald Bellhouse, Dr. R. A. Bolam, and Miss E. Kelly, president

of the Instituto of Industrial Welfare Workers, suitably responded. Sir Henry Craik and Dr. Fremantle, who should have spoken to this toast, were unfortunately compelled to leave early owing to Parliamentary duties.

### OLD AND NEW HAMPSTEAD.

HAMPSTEAD savours of romance. The Heath, Jack Straw's Castle, the Spaniards (with its memories of Dick Turpin and of Mr. Pickwick), the Bull and Bush—the names suggest old times and old doings. Moreover, in the seventeenth and eighteenth centuries the Hampstead chalybeate springs (now dried up, and commemorated only in Well Walk and Flask Walk) were held in high esteem for their supposed curative virtues. In a lecture on the health of Hampstead, past and present, delivered in 1923 and now published, Dr. F. E. Searse, the medical officer of health for the borough, discourses on Hampstead, not only as it is, but as it was. He explains that the hill of Hampstead is formed by a huge elevation in the bed of the London clay, which there supports an extensive cap of sand, in some places eighty feet thick. This rendered it easy to get water; whereas from the line of what is now Oxford Street, northwards to the foot of Hampstead Hill, there was only a great expanse of non-water-bearing clay. Thus, with its water supply old Hampstead was a place apart, and until the water companies came London could not extend in that direction. But from the sandy height streams took their rise. One, the Kilbourne, ran across Finchley Road, along what is now West End Lane, and turned westward near the old Kilburn Wells, to become a tributary of the Westbourne, whose course in Hyde Park is marked by the Serpentine. To-day the curiously winding course taken by the bus-frequented West End Lane is perhaps to be explained by the meanderings of the Kilbourne. Another stream, the Tybourne, rising in the conduit spring on the southern slope below Hampstead village, followed the line of the present Fitzjohn's Avenue, ran down through Belsize, skirted the west side of Regent's Park, and crossed Oxford Street and Piccadilly on its way to join the Thames at Westminster. On the east side arose the Fleet River, or Halebourn (whence Holborn), whose main source was a stream fed by springs issuing from the higher parts of Hampstead Heath. Such water-courses, as time passed, were turned into sewers, which received the waste water resulting from the supplies by the new water companies. It is all very interesting, but we cannot follow Dr. Searse in his story from ancient to modern, nor refer to the instruction he imparts as to the value of the present-day public health system which has developed from these humble beginnings, when (to use the words of the first medical officer of health) the very ground was "saturated with the faeculence of ages." If we venture on a word of criticism, it is to express regret that so good a pamphlet has been issued without correction of a few slips.

### ANKYLOSTOMIASIS AND BILHARZIASIS IN EGYPT.<sup>1</sup>

ANKYLOSTOMIASIS has been endemic in Egypt probably since the time of the ancient Egyptians; but it is only since 1847 that the hookworms have been regarded as pathogenic. At the beginning of this century Looss wrote his famous memoir on the anatomy and life-history of the parasite, but until recently little exact knowledge of the incidence of ankylostomes in the country was available. Bilharziasis is likewise a very ancient disease—indeed, the characteristic ova of the parasite have been found in the kidneys of

mummies of 1250 to 1000 B.C. The disease was known from the earliest times, but its parasitic nature was unsuspected until 1852. The search for the secret of the life-history was unsuccessful until the war period, when Leiper's brilliant investigation not only solved this problem, but also proved that the urinary and intestinal forms of the disease were due to two different species of worm. Although little was known of the incidence of the disease before 1913, it was regarded as the most widespread serious malady in Egypt. Towards the end of 1913, the Department of Public Health, on the initiative of Lord Kitchener, appointed a committee to conduct a campaign against ankylostomiasis, and to investigate the spread of bilharziasis and pellagra. During 1914 and 1915 it was ascertained that the parasite was present in about three-quarters of the population, and the possibility of treating ankylostomiasis on a large scale was demonstrated. The infections with schistosoma, however, were only recorded from statements by patients—a method since found to be almost valueless. The committee suspended operations in April, 1915, and it was not until 1919 that it again resumed its activities. During the interim Leiper had discovered the intermediate hosts of the bilharzia worm, and Cristopherson had found that tartar emetic was a specific for the disease. The work of the committee was extended to include the treatment of the flukes as well as the hookworm. The reconstituted committee under Dr. Todd held its first meeting in January 1921, and commenced to attack the problem of these two diseases. Various annexes, situated close to general hospitals, were started at Government expense for the treatment of the diseases, and patients were examined for the presence of parasites and treated accordingly. During the period from 1920 to 1923 over 100,000 cases have been treated at these annexes. At the same time a considerable amount of propaganda work was undertaken by means of leaflets and posters; some of these, reproduced in the report, are most effective and instructive. The investigation section was under the direction of Dr. M. Khalil, who proceeded to Egypt in November, 1922, from the London School of Tropical Medicine, and who, in addition to a considerable amount of personal research, is mainly responsible for the present report. His confirmatory experiments on the use of carbon tetrachloride as an anthelmintic show that it is, if pure, a safe and valuable drug to use against hookworm and pinworm, although of doubtful efficiency against ascarids. He has also conducted a large series of experiments on the control of bilharziasis. His recommendations are practically the same as those suggested in 1918 by Leiper, with the additional application of the recent use of copper sulphate in high dilution for the destruction of the molluscan intermediary of the parasite in the water in which it lives. In a survey undertaken at one village to provide an index to the parasitic infection among the Egyptians, Khalil found that only 4 per cent. of the inhabitants were free from parasites, and that 73 per cent. harboured *Schistosoma haematobium*, 34 per cent. *S. mansoni*, 64 per cent. ascarids, and 16 per cent. hookworms. This low incidence of hookworm is not the rule in Egypt; its prevalence appears to be very irregular. In a second survey in Upper Egypt about 75 per cent. of those examined showed the presence of *S. haematobium*; no infection with *S. mansoni*, the cause of intestinal bilharziasis, was, however, found, although several cases of intestinal infection with *S. haematobium* were detected. The absence of *S. mansoni* was confirmed by the absence also of planorbis snails, the specific intermediary, from the canals and drains of the district. The most recent statistics accordingly show that about 75 per cent. of the inhabitants of Egypt are affected with bilharzia worms, and the direct mortality is estimated to be about 8 to 25 per cent. of the total deaths; the infection also predisposes to dysentery and other diseases. The report is an extremely valuable

<sup>1</sup> Reports and Notes of the Public Health Laboratories, Cairo, No. 6: *Ankylostomiasis and Bilharziasis in Egypt*. Government Publications Office, Ministry of Finance, Dawson, P.O., Cairo. (Pp. 126. Price P.T. 20.)

APRIL 11, 1925]

contribution to the parasitology and public health of Egypt. It is unfortunate, however, that an otherwise excellent production should be somewhat marred by many misprints. The Public Laboratories in Cairo are to be congratulated on the possession of such a valuable worker as Dr. Khalil, whose energy has made this volume possible.

# JEAN PECQUET.

JEAN PECQUET, the tercentenary of whose birth was celebrated at his native town of Dieppe in 1922, has hitherto been principally known as the first to describe the receptaculum chyli, which is called in Franco the "citerno de Pecquet." Dr. Jean Lucq, who has devoted his inaugural thesis to the study of the life and work of this eminent French anatomist, claims that Pecquet is entitled to a more important place in the history of anatomy, and that he is to be credited with the discovery of the circulation of the chyle. Previous observers, from the time of Galen, had maintained that the chyle was conveyed by mesenteric veins to the liver, where it was converted into blood. Even Asellius, who discovered the lacteal vessels in 1622, was of opinion that they emptied themselves into the liver. In his *Experimenta nova anatomica*, published in 1651 while he was still a student in Paris, Pecquet gave the first description of the receptaculum chyli and the passage of the chyle through the thorax into the innominate vein. His discovery was met by incredulity, especially on the part of Riolanus, who attacked him with considerable bitterness, suggesting that the dogs he had been dissecting had made him mad; but the Danish anatomist Bartholin, after some hesitation, confirmed Pecquet's observations. Lo Noble, a physician of Rouen, endeavoured to conciliate both sides by suggesting that part of the chyle was distributed to the heart and part to the liver, but the opposition to Pecquet ceased after the death of Riolan in 1657. Dr. Lucq is inclined to discredit the accusation of alcoholism brought against Pecquet in his latter years, though this factor may have contributed to his death at the comparatively early age of 52. Apart from his anatomical investigations, Pecquet took some part in the political life of the time in his capacity of friend and medical attendant to the celebrated superintendent of finance Nicolas Fouquet, whose imprisonment he shared for over three years. Subsequently Pecquet became the medical adviser of Madame de Sévigné, who makes several allusions to him in her letters.

## MEDICAL SOCIOLOGY AT THE BATH ANNUAL MEETING.

THE officers of the Section of Medical Sociology in the forthcoming Annual Meeting of the British Medical Association at Bath have now drawn up the programme of work in their Section on the day allotted to it—Friday, July 24th. The morning session will be given up to a discussion of the question, "What should be the standard of purity of milk?" This will be opened by Dr. R. Stenhouse Williams, of the National Institute for Research in Dairying, Reading; from the point of view of the medical officer of health by Dr. W. G. Savage, M.O.H. for the county of Somerset; and from the dietetic point of view by Dr. Eric Pritchard. An allied subject—By what means can pure milk be obtained, and at what cost?—will be debated also from three aspects. Mr. Wilfred Buckley, of the National Clean Milk Society, will open from the standpoint of the producer; Mr. G. P. Maggs from that of the distributor. Cinematograph films of certified milk on an English farm and the handling and distribution of milk in New York City.

## England and Wales.

### ROYAL VICTORIA INFIRMARY, NEWCASTLE.

THE most prominent feature of the work of the Royal Victoria Infirmary, Newcastle-upon-Tyne, during 1924 was the overwhelming demand for beds. The number of in-patients treated during the year, 12,865, was the highest yet reached, and was an increase of 706 over the previous year, which also was a record. The number of patients awaiting admission to hospital at the end of 1924 was 1,202. Although the normal bed accommodation is 534, there was a daily average occupation of 539, and as high a number as 589 had been recorded. To provide for this extra number of patients additional beds had to be placed in the wards, on some occasions more than fifty beds being brought into use during a single week. These conditions necessarily resulted in an injurious shortening of the duration of the treatment of in-patients. Similar difficulties were experienced in 1913 and 1918, while in 1920 the strain continued to be felt in spite of the fact that two extra wards, each containing twenty-six beds, had been added to the hospital. The overcrowding was particularly marked in the wards for women and children. The two factors which mainly contributed to the large increase in the number of in-patients were the severity of the accidents brought to the hospital and the number of cases in which immediate operation was required. During the year under review, 17,352 accident cases were treated, a daily average of 47; of these cases, 1,909 required admission to the hospital. A special inquiry made by the House Committee led to the belief that 75 per cent. of the motor accidents dealt with by the hospital were of such a serious character as to require admission. The committee, therefore, placed the facts before the City Council in the hope that it might be possible to reduce these figures, and also to obtain more financial support from the City Council, since 70 per cent. of the out-patients and 42 per cent. of the in-patients concerned had met with their accidents in the streets of Newcastle itself. The total number of out-patients was 110,525, an increase of 5,000 on the previous year. The total subsequent attendances of these patients reached 189,049. A balance of over £7,000 remained after meeting the year's expenditure, and this had been used to relieve the overdraft at the bank. An increase in subscriptions and donations had occurred, and the endowment fund had been raised by £4,000.

### BIRMINGHAM HOME OF REST.

Dr. Mary Sturge Memorial Wing. The Lord Mayor of Birmingham opened a new nurses' home at the Taylor Memorial Home of Rest, Sparkhill, on April 1st. The extension is to be known as the Dr. Mary Sturge Memorial Wing, in remembrance of the deep interest she always took in the work of the institution, and during her active life had initiated the scheme for the erection of a nurses' home. The cost of the new building was between £3,000 and £4,000, of which £400 had been received in response to an appeal composed by Dr. Sturge not long before her death. Mr. Christopher Martin, F.R.C.S., who presided, said that the home was established in order that poor women suffering from inoperable malignant disease might be nursed and made as comfortable as possible. He referred to Dr. Mary Sturge's ardent and enthusiastic support of the institution since its foundation, and said that her dying request to her relatives was that all possible help should be afforded in support and maintenance of the home. It was felt that the best memorial they could give to her was to open a Dr. Mary Sturge Memorial Fund, the object of which would be to pay for the extension and to provide an endowment fund to carry it on and to increase its usefulness. A letter was read from Mr. W. H. Sturge, stating on behalf of his brothers and sisters that they desired to give £1,000 in memory of their sister, with the object of providing accommodation for more patients, in accordance with her wishes. In declaring the extension open the Lord Mayor paid tribute to the work and devoted service of Dr. Sturge, who, he said, never spared herself when the opportunity occurred.

for helping those in distress. Subscriptions to the Dr. Mary Sturge Memorial Fund may be sent to Mrs. H. C. Ashton (honorary secretary), or to Mr. C. H. Saunders (honorary treasurer), at the Taylor Memorial Home, Showell Green Lane, Sparkhill, Birmingham.

#### THE IMPORTATION OF FOOD.

The Minister of Health has issued a new series of regulations<sup>1</sup> dealing with imported food, which will come into force on June 1st. These regulations amend and consolidate the previous regulations of 1908 and 1909, which have been extended so as to apply to importations of food by train-ferry service and by aircraft. The enforcement in the case of these services is entrusted to the sanitary authorities for the areas where the food is unloaded from the railway truck or aircraft. The provisions for dealing with food found on examination to be unsound are substantially the same as in the previous regulations, but a new clause makes it a definite offence to import any food which has at any stage in its preparation been contaminated in another country. Two schedules deal with classes of overseas meat made subject to special control. The first schedule includes a list of prohibited meat, and special attention is drawn to cases where there is evidence that one of the deep-seated lymphatic glands has been deliberately removed; such meat may not be imported under any conditions. The second schedule deals with meat conditionally admissible; where, for instance, a part has been cut off so as just to exclude one of these glands, such a part may be admitted if accompanied by an official certificate, except in the case of heads cut off so as not to include submaxillary glands. An official certificate is now required for lard, dripping, edible tallow, and other rendered fats. The official certificates of certain countries have already been recognized, and before the new regulations come into operation a notice will be inserted in the *London Gazette* specifying all the certificates which will be recognized from the date of commencement. A further circular will then be issued containing a copy of the notice.

#### NATIONAL LEAGUE FOR HEALTH, MATERNITY, AND CHILD WELFARE.

The National League for Health, Maternity, and Child Welfare originated in 1905, and now includes the National Association for the Prevention of Infant Mortality, the Association of Infant Welfare and Maternity Centres, the National League for Physical Education and Improvement, the National Baby Week Council, the National Society of Day Nurseries, the National Council for the Unmarried Mother and her Child, and the Women's National Health Association of Ireland. During the past year particular attention was paid by the league to extension of the child welfare movement, and a list of suggestions sent to the Ministry of Health contained recommendations for the teaching of biology to school girls, as a foundation for subsequent teaching in hygiene and mothercraft. It was also recommended that there should be more extensive provision of facilities for the diagnosis and treatment of venereal disease, and for convalescent treatment for mothers and children, more dental clinics, nursery schools, and hospitals for illegitimate children. Health lectures were given to the members of working girls' clubs—twenty-five in the provinces and ninety-six in London. It is proposed to organize free courses of popular lectures on general health topics, the expenses to be borne by the Women's Imperial Health Association Fund. A cinematograph film is to be prepared to illustrate such activities as swimming, field and playground games, drilling, sports, and the physical training of adolescents. It is announced that this film will be lent, free of charge, to local education authorities, or to any other organization which can provide an audience of parents, teachers, and others interested. The library of the league has received a considerable number of new books dealing with child care, psychology, and heliotherapy. The annual report of the league for 1924 states, further, that the sale of the league's publications during last year has passed all previous records, the total income resulting therefrom

being over £2,000, which has been of the greatest value in carrying on the work of the league. The fourth edition of *Mothercraft*, published at the end of February, 1924, was almost entirely sold out by the end of the year, and the fifth edition has now appeared. The "Tired Mothers Holiday Fund" has provided forty-three grants, an increase of ten over the previous year. The league's report contains the annual report of the associated societies, and a statement of accounts for 1924.

## Scotland.

#### VOLUNTARY ADMISSION OF RATE-AIDED PATIENTS TO MENTAL HOSPITALS.

THE board of direction of the Crichton Royal Institution, Dumfries, has presented a memorial to the Secretary for Scotland urging the importance of making suitable statutory provisions so that rate-aided patients may be admitted as voluntary patients to mental hospitals in Scotland. The memorial points out that the present Scottish Lunacy Acts are defective in so far as they debar the rate-aided or poorer classes of the community from receiving treatment as voluntary patients in the public mental hospitals of the country. This involves the postponement of treatment until they have become certifiable as insane, and in many cases such patients become, as the result of the delay, incurable. In the Crichton Royal Institution approximately two-thirds of the patients are private and one-third rate-aided. The private patients, who are maintained by themselves or their relatives, are received either as voluntary patients or under certificates of insanity. A great change has taken place in the relative proportions of these two classes since 1908, when the reception of voluntary patients began. Previously, about 20 per cent. of the private admissions were voluntary and 80 per cent. were certificated. Since 1908, 70 per cent. of the private patients admitted are voluntary and only 30 per cent. under certificates. As a result, while there were 21 voluntary patients in residence on December 31st, 1907, there were 212 on December 31st, 1924. Experience at the institution has gradually proved that the great majority of patients can be treated suitably in a mental hospital under the voluntary procedure, which has the great advantage of encouraging earlier treatment, and is more attractive to the patients as well as to the relatives and all concerned than the alternative of certification with its legal and other disabilities. In contrast to the private patients, the rate-aided patients are all admitted under certificates of insanity from the various parishes of Dumfriesshire and Galloway. A tabular statement is presented in the memorial comparing the results of treatment among the private voluntary, private certified, and rate-aided certified groups. The results of treatment are shown to be better among the voluntary than among the certified of the private class, for the reason that the former exhibited in larger proportion illnesses of less serious type and more recent duration. The great majority of private patients had been previously treated in nursing homes and private houses, whereas the rate-aided patients were sent direct from their homes in nearly all cases. It is pointed out that the more favourable results of mental hospital treatment among private as compared with rate-aided patients from a city may to some extent be explained by the difference in the previous mode of life and social environment of the two classes, but this consideration is hardly applicable to rate-aided patients from the healthy rural areas of Dumfriesshire and Galloway, amongst whom it might have been expected that the results of treatment would have been even better than among the private class. On the contrary, it was found that the recovery rate (or number discharged as recovered per 100 admitted) of the private voluntary group exceeded that of the rate-aided certificated group by 9.2 per cent. If those discharged as improved were included with those discharged as recovered, the rate for the private voluntary group exceeded that for the rate-aided certificated group by 23.3 per cent. The memorial expresses the belief that on a conservative estimate the

<sup>1</sup> Statutory Rules and Orders, 1925, No. 273. London: H.M. Stationery Office. S.L. n.2.

results of the treatment of rate-aided certified patients would be 10 or 15 per cent. better if they were admitted as voluntary patients, and that this was worthy of consideration, not only from the humanitarian aspect, but also from the point of view of the national welfare. Under the present arrangements, rate-aided patients can be legally admitted for treatment as voluntary patients in Scottish asylums, but there is a practical bar to their admission in the fact that the lunacy grant is paid to parish councils towards the cost of "pauper lunatics" only, and parish councils have been reluctant to lose the benefit of the grant (as they would) if rate-aided patients were admitted as voluntary patients to asylums. Consequently, they have not encouraged the voluntary system. It may be recalled that in our issue of March 7th (p. 475) it was pointed out that certain parishes, notably in Argyllshire and recently the Edinburgh Parish Council, had decided that the poor should be put in a position to enjoy the advantages of voluntary treatment notwithstanding that this involved relinquishing the grant-in-aid. The memorial considers it only fair to expect that if the disabilities mentioned were removed and the early treatment of mental diseases was encouraged in the ways indicated, rate-supported mental patients would in time come to the mental hospitals at least as willingly as private patients at present, and perhaps eventually with no more reluctance than the rate-aided inmates of fever hospitals and sanatoriums.

**MEMORIAL TO THE LATE DR. C. B. KER.**  
A subscription list has been opened to provide a memorial to the late Dr. C. B. Ker, medical superintendent of the City Hospital, Edinburgh, and a circular has been issued to all past and present members of the medical and nursing staffs of the hospital whose addresses are known inviting them to contribute. The appeal is being issued in the names of Dr. Alexander James, the consulting physician to the hospital; Dr. William Robertson, the medical officer of health for the city; Miss Thomas, the matron of the hospital; and Dr. A. Joe, the senior assistant. It is proposed that the memorial should take the shape of a monument at Dr. Ker's grave in Morningside Cemetery, and, if funds permit, the erection of a plaque in the hospital, both in this country and abroad, who will be desirous of contributing, but whose addresses are not known, and all such are invited to send donations to Mr. Macdonald, steward, City Hospital, Edinburgh.

**PHYSICAL EDUCATION IN SCOTLAND.**  
The annual general meeting of the Association of School Medical Officers, held in Edinburgh on March 23rd, was addressed by Colonel V. E. Gooderson, D.S.O., superintendent of physical education to the Glasgow Education Authority. Physical education was, he said, an aspect of the larger problem of general education, and real physical education could not be relegated to gymnastics and games alone. Physical education might be so conducted as to set a standard of living and behaviour that would surpass the average, and, like moral instruction, in order to be effective, its spirit must pervade the entire curriculum. There should be more appreciation of the value of an active physical life, and the teacher of physical education must know the physical, psychic, and social characteristics of children and the time and manner of their development. Facilities should be provided for all children to express themselves in spontaneous play, but it was also desirable that much in the way of physical and moral development should be obtained by directed play and organized physical expression. Systematic organized play impressed the ideals taught by organization and co-operation. Games, athletics, dancing, and swimming were all special forms of controlled physical education and were found more controlled part of physical education was to be found in gymnastics. Gymnastics had a twofold aim—corrective and developmental—and might form a preparatory treatment to surgical measures and also serve as a necessary after-treatment. This part of physical education was worthy of more thorough scientific investigation. Instruction in healthy living and physical efficiency should be related to life rather than to physiology and anatomy.

Instruction in hygiene might, to some extent, be correlated with biology and nature study, but it should chiefly collect information regarding the art of preserving a sound body. Only four out of thirty-seven education authorities in Scotland had yet appointed a superintendent of physical training, and five county authorities were still without a single teacher of physical education. Medical examination of children was providing records of size, growth, abnormality, and illness, but not much information was available regarding the relation between physical and mental ability. He thought that peculiarities in mental development might depend upon corresponding changes in physical or physiological development.

**DEACONESS HOSPITAL, EDINBURGH.**  
The annual meeting of the Church of Scotland Deaconess Hospital, Edinburgh, was held on March 31st. Professor Archibald Main, D.D., presided, and Lord Sands, chairman of the hospital board of management, submitted the annual report. The total number of patients during 1924 had been 5,762. The number of patients treated in the hospital had been somewhat less than previously owing to closure of part of the hospital for some months for reconstruction, but had totalled 705; the number of operations performed had been 625. This number included patients from all over Scotland, including Orkney, Shetland, and the Outer Hebrides. In the children's ward 124 infants, as well as 107 older children, had been treated. A large number of these were received in connexion with the maternity and child welfare scheme of the Edinburgh Public Health Department. The number of out-patients treated during the year had been 4,849, with a total attendance of 15,672. The total income, including that from investments, was £5,576, while the total ordinary expenditure chargeable against income had been £5,541. This leaves the hospital in the satisfactory position of having a small surplus. This, the chairman not be said of many hospital budgets. Every bed that was endowed lightened the annual burden, and he appealed for further public support in this direction. During the past year an annexe had been added at a cost of nearly £3,000, which was partly defrayed by special subscriptions and partly chargeable to the capital reserve fund. The total sum received from approved societies for treatment of insured persons during the thirteen years since the Act of 1912 came into force had amounted to less than £65, although during the last year alone no fewer than 124 insured persons had been treated in the hospital. In view of the obvious inadequacy of the sums thus received from approved societies in the past in recognition of the benefits conferred by the hospital on their members, the board had again decided not to accept any similar payments in the future, but to treat all insured patients without any payments by approved societies on their behalf. The report was adopted on the motion of Mr. W. J. Stewart, F.R.C.S.E., consulting surgeon to the hospital. Mrs. R. K. Hannay moved a vote of thanks to the staff, to which Dr. John D. Comrie, physician to the hospital, replied. Votes of thanks to the subscribers and chairman respectively were moved by Dr. W. G. Sym and Town Councillor Dr. T. G. Nasmyth.

#### MESSAGE AS AN ADDITIONAL BENEFIT FOR INSURED PERSONS.

At the annual meeting of the Edinburgh, Leith, and District Friendly Societies' Council, held in Edinburgh on March 28th, an address on message and allied treatments as an additional benefit for insured persons was delivered by Miss E. W. Binning, honorary secretary of the Edinburgh Committee of the Chartered Society of Massage and Medical Gymnastics. A scheme, she said, had been proposed to provide for the keeping of a register of members of the Chartered Society of Massage who were willing to provide treatment for insured persons at a flat rate, and also for the organization of clinics for a similar purpose. Such treatment would only be given by members of the society under the orders of a registered medical practitioner. A report was presented by Mr. Thomas J. Addy, embodying the views of the approved societies affiliated to the council for submission to the Royal Commission on National Health

**Insurance.** This report was said to represent the collective opinions of 100,000 insured persons in the district obtained by a series of special meetings for discussion of national health insurance.

#### EMPLOYMENT FOR DEAF AND DUMB.

The eighty-fourth annual meeting of subscribers to the Edinburgh Deaf and Dumb Benevolent Society was held on March 25th. Baillie Couston, who was in the chair, said that now that the society had entered into extended premises, which he hoped meant increased activities, subscribers had increased from both town and country. It was very difficult for the ordinary employer to find a niche for the people among whom the society worked, but there must be many openings for shoemakers, tailors, and other employments for which they were fitted. Sheriff J. L. Wark, K.C., said that there were on the roll of the society more than 600 names of deaf and dumb, some also blind, resident in Edinburgh and district. A home for the society's aged and infirm was urgently needed, and the directors hoped in the near future to be able to realize this long-desired want.

#### SMOKELESS FUEL IN SCOTLAND.

At a conference of the Scottish District of the British Commercial Gas Association, held on March 24th in the Town Hall, Greenock, reference was made to the damage done to health by the pollution of air by smoke. Baillie Millar of Greenock, who presided, gave an address, in the course of which he said that a young Scotsman named Murdoch had been the first to light his house in Cornwall, in the year 1792, with coal gas, so that it was well over a century since gas was first used as a means of illumination. The centenary of the use of gas in Greenock would be celebrated two years hence. At the afternoon session Dr. J. H. G. Whiteford, medical officer of health for Greenock, delivered an address on atmospheric pollution in relation to health. The most efficient epidemic officer was sunlight, which cost the community nothing, and which, when germs were few in number and had not been allowed time to increase, was most effective. This made out an excellent *prima-facie* case for action in regard to smoke abatement. Mr. John Keiller dealt with the contribution of the gas industry towards reducing atmospheric pollution. The only way to put an end to the free pouring out of smoke into the atmosphere was to cease burning coal in its raw state, whether in the factory or in the home. This could be done by treating coal before using in such a way as to produce completely smokeless fuel. The gas produced from coal was clean, smokeless fuel, far more efficient than the coal itself; and in its production there were recovered coke and many other valuable by-products which were used in the manufacture of drugs, fertilizers, perfumes, dyes, and scores of important chemical products. These by-products, if coal was burned raw, were either destroyed at low efficiency or sent up the chimney unburned in the form of smoke and noxious vapours. Dr. C. W. Saleeby in the evening delivered a lecture in which he spoke of the brilliance of the light and clearness of the air in Canadian and American cities as compared with British cities. He did not propose that all houses should be reconstructed to accord with ideas for the abatement of smoke, but it would be reasonable to begin right with the two million houses which the Ministry of Health had promised to construct. The question of smokeless housing had been solved in recent schemes at Luton and Dundee.

## Ireland.

#### LOCAL GOVERNMENT ACT, 1925: IMPORTANT PENSIONS SECTIONS.

The Local Government Bill (Irish Free State) has been passed by the Dail and Senate and is now law. Since its introduction into the Dail its pensions sections, as the result of representations made by the Irish Medical Committee, have been modified to the advantage of officials generally, especially Poor Law medical officials. The pension rights of an existing medical officer, who was in office at the

date of the passing of the Act, and at that date had more than ten years' service as an officer of a local body, can, for the purposes of his pension, choose to remain under Section 8 of the Local Government Act, 1919. It will, however, be necessary for a medical officer who desires to be pensioned under Section 8 of the Act of 1919 to signify in writing within four months after the passing of the Local Government Act, 1925, to the body of which he is an official, that it is his intention *not* to avail himself of all the provisions of Part IV of the Local Government Act, 1925. In the event of a medical officer selecting Section 8 of the Local Government Act, 1919, for pension purposes, Sections 43, 46, 49, 50, 53, 54, 55, and 56 of the Local Government Act, 1925, nevertheless, will be applied to him. These sections do not adversely affect the pension rights of existing medical officers as defined under the Act. For existing medical officers, with less than ten years' service, and future officers the mandatory right to a pension, for the first time provided under Section 8 of the 1919 Act, has been restored to the 1925 Act, and it is not possible under this Act for any local body to refuse a pension to an official without the consent of the Minister. In this respect Section 44 (1) provides:

A local body shall, with the consent of the Minister, grant to a pensionable officer in their employment, who either—

(a) has attained the age of 65 years and has at least twenty-five years' service, or

(b) becomes incapable of discharging the duties of his office with efficiency by reason of permanent infirmity of mind or body, or of old age, and has not less than ten years' service, upon his resigning or otherwise ceasing to hold his office an annual allowance for his life not greater than two-thirds of his yearly salary and emoluments.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons adjourned on Thursday, April 9th, for the Easter Recess, after a week spent chiefly in advancing minor legislation. It reassembles on April 28th, when the Budget will be introduced. The second reading of the Therapeutic Substances Bill was moved on April 6th, but objection was taken and the bill was postponed.

Lord Sydenham gave notice that in the House of Lords on April 6th he would call attention to the grievances of the Indian Medical Services, but he did not pursue the subject. Lord Amthill that day drew attention to the case of civil servants employed by Indian provincial Governments, and Lord Birkenhead, the Secretary for India, promised to look into it.

The Cabinet is understood to have decided that the Factories and Workshops Bill should be introduced before Whitsun and passed into law this session. Its text was considered on April 6th by the Home Affairs Committee of the Cabinet.

#### Factories and Workshops Bill.

On April 2nd the Medical Committee of the House of Commons met representatives of the British Medical Association and of the certifying factory surgeons to discuss the bearing which the Government's promised Factories and Workshops Bill would have upon the health administration of the country. Opinions were exchanged on the proposed replacement of the system of certifying factory surgeons by "works doctors," either in the employment of the local authorities or appointed by the Ministry of Health. After two hours' discussion of various points it was agreed that the bill as a whole should be supported, but that further consideration of several points in dispute should be postponed until the new version of the bill appeared. No agreement was reached on the particular point, though all were ready to support the bill as a whole. Those attending this conference, over which Dr. Fremantle presided, included Dr. Brackenbury, Dr. Cox, Dr. Wallace Henry, Dr. Bolam, Mr. E. B. Turner, Dr. Courtenay Lord, Dr. Dearden, Dr. Ridley Bailey, and Dr. Beadles.

#### Health in Scotland.

The House of Commons, on April 6th, debated in Committee the Estimates for the Scottish Board of Health. The Under Secretary of Health for Scotland, Dr. Walter Elliot, said the House was reviewing the vital statistics of an industrial State swept by the full blast of unemployment; 181,000 people totally without work were living on relief, and the fear of anyone responsible for the health of the country was that lowered vitality would be shown in a movement of all sickness curves. Unemployment was now somewhat greater than at the same period last year. Public health last year was unsatisfactory.

APRIL 11, 1925]

The movement of vital statistics was adverse. The year 1923 was the healthiest on record in Scotland, with a death rate of 12.9 per 1,000, but last year it rose to 14.4. Infantile mortality moved from 79 in 1923 to 93 per 1,000 in 1924, and insurance returns showed an increase of 15 to 20 per cent. in sickness last year. Yet although the general death rate moved adversely, the tuberculosis statistics were unchanged, or slightly more favourable. It seemed that in Scotland the sickness curves moved unfavourably owing to an epidemic of influenza in the early part of 1924, and the position now was not as bad as the figures suggested. The investigations did not bear out the suggestion that the long period of unemployment was having a bad effect. Increased infantile mortality seemed to have been due largely to epidemics, which were now slackening. The infantile death rate, which was 132 in the first quarter of this year under review, would fall to 109 in the first quarter of 1925, and it might be expected that this year would be healthier for infants than last. The increase in the sickness rate was paralleled in England, where the general death rate had increased by 0.6; in France, also, there was an increase of 0.3 in the death rate though there was no unemployment, and Denmark showed an increase of 0.1. A wave of ill health had passed over Western Europe last year. Some people said that it was due to the sunless summer. In Scotland, for whatever reason, £40,000 more had been spent on drugs than last year. The measles grant, the increased grant for pneumonia and bronchitis, the investigations, were steps taken to improve the organism had been discovered, were steps taken to improve the public health. Infective jaundice had been shown to occur not only among miners, but among the general public, where it had sometimes been attributed to ill health following influenza. It also occurred in dogs after distemper. It had been made a notifiable disease in Scotland.

Dr. Drummond Shiels, speaking of tuberculosis, said that there was not a subject for congratulation. I encourage his department, it tested.

Dr. Drummond Shiels, speaking of tuberculosis, said that its general incidence was not a subject for congratulation. In the Spallinger treatment there was at least a ray of hope, and he asked Dr. Elliot to encourage his department to co-operate with the Ministry of Health to get it tested. He also drew attention to the need for light treatment centres; Scotland was behind in that matter. He referred to tuberculous milk, and declared that ungraded milk was now of poorer quality than when the grading system was introduced.

**Registration of Deaths.**

Dr. Fremantle, after discussion with the Medical Committee of the House of Commons, has sent the text of the Births and Deaths Registration Bill to be printed. A memorandum states that the object of the bill is to render the law of the certification of death at once simple and complete, so as to leave no room for certification on insufficient evidence, and to eliminate so far as possible all risk of premature burial or failure to detect crime. Provision is made for medical inspection of the body in all cases before certification of the fact of death, and for adequate inquiry before certification of its cause. The bill would require stillbirths to be certified and registered. Relevant clauses are:

*Certificate of Fact of Death.*—(1) A medical certificate of birth or stillbirth shall be given by a registered medical practitioner, who has viewed and examined the body of the child, and is satisfied that it is dead. (2) Such practitioner,

3. *Medical Certificate of Fact of Death.*—(1) A medical certificate of the fact of every death or stillbirth shall be given by a registered medical practitioner who has viewed and examined the dead body and is satisfied that life is extinct. (2) Such practitioner shall, whenever reasonably possible, be the practitioner, if any, who last attended the deceased person during life or was present at the stillbirth. (3) If no such practitioner so attended the deceased or was present at the stillbirth, it shall be the duty of the person legally responsible for notifying the death in accordance with Section 10 or Section 11, as the case may be, of the Births and Deaths Registration Act, 1874, to secure a registered practitioner to certify the fact of death or of stillbirth in accordance with this Act. (4) If such person for any reason is unable to secure the services of a registered medical practitioner for the purpose aforesaid, then it shall be the duty of that person for the purpose of the district in which the death or stillbirth occurred of this fact, and a registrar receiving such information shall within twenty-four hours thereafter inform the coroner of the said district, whose duty it shall then be to appoint a registered medical practitioner for the purpose.

4. *Medical Certificate of Cause of Death.*—(1) A medical certificate of death shall be personally given by a registered medical practitioner who attended the deceased person during life or was present at the stillbirth, if any, who last attended the deceased person during life or was present at the stillbirth, it shall be the duty of the person legally responsible for notifying the death in accordance with Section 10 or Section 11, as the case may be, of the Births and Deaths Registration Act, 1874, to secure a registered practitioner to certify the fact of death or of stillbirth in accordance with this Act. (4) If such person for any reason is unable to secure the services of a registered medical practitioner for the purpose aforesaid, then it shall be the duty of that person for the purpose of the district in which the death or stillbirth occurred of this fact, and a registrar receiving such information shall within twenty-four hours thereafter inform the coroner of the said district, whose duty it shall then be to appoint a registered medical practitioner for the purpose.

**4. Medical Certificate of Cause of Death.**—(1) A medical certificate of the cause of death shall be given by a registered medical practitioner wherever possible during life, and if no such practitioner has attended the deceased person professionally during life, or the person so attending is unable to give or does not give the registrar to report the fact to the coroner of the district in which the death has occurred, and it shall be the duty of the registrar upon receiving such a report from the coroner of the district to satisfy himself concerning the cause of death and to issue the said certificate of the cause of death to the registrar, forthwith.

(2) A registered medical practitioner shall not be required to certify the contents of the stomach, intestines, or other organs of a deceased person, for the purpose of ascertaining the cause of death, if he states that he is unable to do so.

(2) A registered medical practitioner shall not be required to make an analysis of the contents of the stomach, intestines, or any other part of the body of a deceased person, for the purpose of establishing the cause of death, if he states that he is unable or unwilling to do so.

13 (3) Nothing in this Act shall affect the provisions of the Anatomy Act, 1832, or any Act amending that Act.

Provision is also made in the bill to ensure the orderly disposal of the dead and to prevent retention of dead bodies before disposal in those cases which are not already covered by the Public Health Acts. The bill, which does not apply to Scotland or Northern Ireland, is backed by Mr. Gerald Hurst, Mr. Morris, Dr. Haden Guest, and Sir Henry Slessor.

*Pensions.*—Colonel Sir Arthur Balfour, Minister of Pensions whether a sessional medical

*Pensions.*—Colonel Sir Arthur Holbrook, on April 1st, asked the Minister of Pensions whether it was intended that ex-full-time medical officers on sessional medical board work should be given preference for such work over medical men who had not been full-time medical officers of the Ministry; and, if so, whether instructions to that effect had been given, or would now be given, to all area deputy commissioners for their future guidance. Colonel Stanley, repeating an assurance given on March 11th, said it was the intention that former full-time salaried medical officers of the Ministry of Pensions should generally be given preference in the allocation of part-time sessional work, and instructions were being issued accordingly.

*Final Awards.*—On April 2nd, Colonel Stanley said that no instructions had been issued to members of the medical boards or the audit staff that the assessment of pensions should be made on the maximum possible basis. Since November 1st the rate of pension had been reduced, and the rate of reassessment during the degree of

**Pensions.**—Colonel Stanley said that no audit staff had been issued to members of the medical boards since November 1st the rate of assessment had been reduced after medical examination in 12,200 cases, or 16 per cent. of the total, and increased in 21,300 cases, or 27 per cent. of the total. The net result of reassessment during the year cent. had been an average increase in the degree of disability of 2.7 per cent. questions defined by the Ministry found had been

period had been an average increase in the net result of the time limit was assessed of 2.7 per cent. In reply to questions on April 2nd, Colonel Stanley said that an erroneous award was defined by the Ministry as an award which, as a result of a course of medical treatment and observation, it was seen to have involved an error of medical diagnosis or prognosis. The cases in which a serious error was suggested were few. Each had to be judged on its merits, and the Minister had no authority to modify a statutory final award where no more than a slight temporary worsening could be shown. For such cases the scheme of final awards included the provision of treatment as an essential feature. Every case where the responsible advisers, medical and other, of the Minister was recommended for a grant of special sanction. The working of the arrangements was being carefully watched, and as the local medical staff of the Ministry understood better the nature of the problem involved their recommendations were found in an increasing majority of cases to be justified. In reply to another question, Colonel Stanley stated that the total number of out-of-time cases which the appeal tribunals thought they were debarred from considering, owing only to the expiration of the time limit was diminishing, but an increasing proportion represented cases in which the man was genuinely prevented by unavoidable cause from appealing within the statutory time. The arrangement for correction of cases in which a final award was found to be erroneous, was, in the opinion of the Minister, adequate.

—*Indian Medical Service*.—Brigadier-General Charteris for India, on April 6th, officers of British applied to the Indian Army, the Indian

*Pay of Indian Medical Service.*—Brigadier-General Charteris asked the Under Secretary of State for India, on April 6th, whether the recent augmentation of pay of British officers in India, both of the British Army and of the Indian Army, applied to all officers except those of the Dental Corps, and the Royal Army Medical Service, tho Army Medical Corps, and the Veterinary Corps; that this was certain to prejudice future recruitments for these essential services in India; and what was the reason for this decision. Lord Winterton replied that officers of the Indian Medical Service in military employ had been granted the same pay concession as those in civil employ, as a result of the recommendations of the Commission on the Superior Civil Services in India, and officers of the Indian Army. The ease recently been granted to officers had been reserved for further consideration, as there was a possibility of changes affecting them of the other services mentioned in a further question by Mr. Buckness.—In reply to a further question by Mr. Buckness (678) as to the high rate of artificial silk manufacture was highly the matter was highly

**Acetone and Sickness.**—In reply to a further question by Mr. Oliver (see April 4th, p. 678) as to the high rate of sickness among operatives engaged in the manufacture of artificial silk from acetone, the Home Secretary said that the matter was highly technical and was still under investigation. The works had been visited by a medical inspector, who reported that a number of the cases of sickness which recently occurred there were influenza, and that the effects of acetone on the workers had not been so serious as represented. He stated, however, that the workers were affected to some extent and that improvements were needed in the arrangements. One of the engineering inspectors would visit in the works this week and advise on the alterations required. As soon as his report was received steps would be taken without delay to secure necessary improvements.

serious as reported. One of the English members were affected to some extent by the arrangements in the works this week and advised steps would be taken soon as his report was received. Improvements in the delay to secure the necessary improvements. On April 2nd, the Homo *Cannabis Indica*.—In reply to questions on April 2nd, the Homo *Cannabis Indica*.—In reply to questions on April 2nd, the Homo Secretary said: (1) That there was no power to postpone the operation of the Order scheduling cannabis indica as a poison. Under the statute, the resolution of the Council of the Pharmaceutical Society for the inclusion of a substance in the poisons schedule took effect one month after the Order of the Privy Council Office approving it had been advertised in the *London Gazette*. As the resolution was passed as long ago as last

August, ample notice had been given to all interested parties, and there did not appear to be any grounds on which the Government could properly intervene now. He was sure that no harsh measures would be taken by the Pharmaceutical Society in the enforcement of the law. (2) That the Government had not heard that any foreign Powers had yet ratified the convention concluded by the second Opium Conference at Geneva. The Central Board proposed in that convention could not come into existence until the convention had been ratified by ten Powers.

**Women Members of Asylum Visiting Committees.**—Sir Robert Newman asked the Minister of Health, on April 2nd, whether over 30,000 women patients of unsound mind were detained in borough and county mental hospitals where there was no lady member on the visiting committee; and whether he proposed to take steps to make it compulsory, if necessary by legislation, that in all public institutions where women of unsound mind were detained there should be some of their own sex on the visiting committees. Mr. Neville Chamberlain replied that the importance of the presence of women on visiting committees was fully recognized, and the matter had already been brought to the notice of the Royal Commission on Lunacy. A clause ensuring the appointment of women visitors had been included in a bill the Ministry of Health introduced in 1923.

**Scarlet Fever Toxin-antitoxin.**—Dr. Fremantle asked the Minister of Health, on April 2nd, if his department and the Medical Research Council had now sufficiently examined the efficacy of the toxin and antitoxin for test, prevention, and cure of scarlet fever, as officially used in several of the United States of America, and with what result. Mr. Chamberlain said that investigations were being actively pursued by the Ministry of Health and by the Medical Research Council, and the results would be published from time to time. These investigations entailed prolonged laboratory and clinical observations before a confident statement could be made of the efficacy of these procedures on the strength of tests in this country.

**Expenditure on Medical Research.**—Mr. John Williams asked the Minister of Health, on April 2nd, the amount of money spent on the prevention and cure of tuberculosis; the amount spent similarly on cancer; and the amount spent on research work for the prevention and cure of disease. Mr. Neville Chamberlain replied that it was difficult to estimate the expenditure from public funds on the prevention of tuberculosis. The estimated gross expenditure on treatment by local authorities during the financial year 1924-5 was £2,850,000. No State-aided scheme was in force for the treatment of cancer. On the co-ordinating Departmental Committee on Cancer at the Ministry of Health £2,300 was spent in 1924-5. The vote for the Medical Research Council in the same year was £140,000, and during that year approximately £5,000 was spent out of the Ministry of Health vote on research work, including the work of the Committee on Cancer.

**The Spallinger Treatment.**—In reply to Mr. Thomas Williams on April 2nd, the Minister of Health said that all practicable steps had been taken by the Ministry of Health to secure, for scientific investigation, a supply of M. Spallinger's preparations for the treatment of tuberculosis, but the Ministry was still without information as to when such a supply would be available in this country. The question of giving financial assistance to any local authority which obtained a supply of this serum for use in its institutions would be considered if and when it arose.

**Approved Societies and Hospitals.**—Mr. Timne, on April 2nd, asked the Minister of Health whether, having regard to the unremunerated services rendered by voluntary hospitals to insured persons, he would bring influence to bear upon the approved societies to make suitable contributions out of the unpaid health insurance surplus to the funds of voluntary hospitals treating insured persons. Mr. Chamberlain replied that for some time considerable sums had been paid yearly by societies to voluntary hospitals out of disposable surplus, and he hoped such sums would be increased in the future. The question would doubtless be reviewed by the Royal Commission on National Health Insurance.

**Insurance.**—The Minister of Health has stated that no occasion has arisen for approved societies to keep statistics of the number of persons in receipt of sickness benefits for each year. In 1924 the insured persons numbered 13,573,000, and £13,028,000 was paid in sickness benefit.

#### Notes in Brief.

Down to March 30th 71 cases of small-pox were notified in the urban district of Kettering, and 7 in the rural district. Of the 78 patients, the vaccinal condition of one was doubtful, 51 were stated to have been vaccinated in infancy, and one at 5 years old. None had been revaccinated, and all, except one aged 25, were over 39 years old.

In reply to a question as to a bill promoted by the Bradford Corporation to acquire certain powers now vested in boards of guardians, Sir Kingsley Wood said that he could not anticipate the Minister of Health's statement on that bill, nor the proposals for the Poor Law reform which the Minister hoped to submit in due course.

The Home Secretary states that he has no power to exempt the provisions of the Lottery Act.

unable to show the number of unemployed nor the number temporarily taken off the through sickness.

In reply to Mr. Clarry, the Office of Works states that in installing a gymnasium at the House of Commons for the purpose of ensuring the health and physical fitness of members would not be practicable.

In reply to Dr. Graham Little, on April 2nd, Sir Burton Chadwick, Parliamentary Secretary of the Board of Trade, said he was aware that certain special types of x-ray apparatus were not introduced in this country, but he was not prepared to introduce a bill removing them from the schedule of the Safeguarding of Industries Act.

Eleven slum clearance schemes have been approved since November 1st, 1924, and sixty-nine in all since January 1st, 1919. Clearance is in progress or complete in sixteen schemes.

The approximate number of beneficiaries from the Ministry Pensions was 3,004,000 in 1921, and 2,080,000 in 1924.

Mr. Neville Chamberlain does not propose to introduce a Milk and Dairies Bill this session.

The Chartered Associations (Protection of Names and Uniforms) Bill, which passed through Committee in the House of Lords on April 6th, is designed to prohibit the wearing by unauthorized persons of the uniforms of nursing and other associations.

The Home Secretary informed Mr. George Harvey on April 6th that he was considering the introduction of a bill to give effect to those parts of the International Convention, signed at Geneva in 1921, on the use of white lead in painting buildings, on which there was general agreement.

The Minister of Health estimates the number of persons between 65 and 70 years of age at 1,029,056.

#### M.P.s and Osteopathy.

A circular signed by twenty-one members of Parliament invited M.P.s to attend a meeting on March 31st to meet the president and other members of the British Osteopathic Association, and to hear an address by Dr. W. Kelman Macdonald of Edinburgh on the objects of the association and the present position of osteopathy. About thirty members of Parliament attended.

Mr. Basil Peto, taking the chair, said there was no recognized school of osteopathy in this country nor any board of osteopathy with the result that the public was exposed to charlatans. Forty-eight States of America this new science was recognized, as there were immense numbers of students. He felt it time that those in the House who were interested in the subject should ask the Ministry of Health to make this new body of knowledge available and to save this country from being a C3 nation. At present the General Medical Council held that the administration of anaesthetic for a manipulative surgeon or osteopath was infamous conduct and rendered the offender liable to the taking away of his degree. Should they not say that the time had come when they must declare there was something more than the ordinary physician's art of healing by drugs? He suggested the establishment of a committee to uphold the interests of osteopaths in the House of Commons and to press for their recognition.

Dr. Kelman Macdonald said that since 1910 he had entirely given up the use of drugs in dealing with the sick, save during service years when he had more or less to conform to orthodox practice. Osteopathy could relieve or cure most diseases by ensuring a good arterial and nerve supply to the tissues and by ensuring that the veins and lymphatics which carried away the waste products remained freely open. It did not matter what the discoveries of the future might be in the chemical or electrical world, the great principle of structural integrity remained, and on it osteopathy was founded. A disturbed artery determined to an hour the onset of disease. He quoted the declaration by Dr. Still, the founder of osteopathy, that all diseases were mere effects. It must be admitted that some of the early schools of osteopathy did not give a tremendously adequate training in general osteopathy. But the American Osteopathic Association now had 4,000 members, and there were seven approved osteopathic colleges in America, each with a four years' course. At present 4,000 persons were taking this course to be osteopathic physicians. The truth was that the osteopathic colleges were attracting the best type of American manhood and womanhood. The Editor of the *BRITISH MEDICAL JOURNAL* looked on osteopathy as a cult, but there were now more than 10,000 osteopaths, so that it was "some cult." Dr. Macdonald went on to explain that "the backbone is the happy hunting ground of the osteopath." The osteopath studied the tissues, but the bones interested him most, and the scientific adjustment of a bone out of place formed the keystone of his therapy. The osteopath banded with special success the treatment of those unfortunate persons called neurotics. The osteopath broke through the vicious circle causing neurasthenia by moving soft tissue and making a lesioned vertebra retrace the path it had taken from normality. Osteopaths were able to treat with success a large number of diseases which had defied the ordinary practitioner. Was it not refreshing that there was a definite framework abnormality to be dealt with when drugs, psycho-analysis, and the short-circuiting of the bowel or the removal of bowel "kinks" had failed? The osteopaths had broken away from the drug-giving school of medicine. They wished to remain outside and to have another fifty years to demonstrate their art. Their discovery would be smothered by the medical profession if the osteopaths were absorbed now, but a change would take place. The fetid bottle of medicine would go. Children died officially of measles, really of bronchopneumonia, because their bodies were not encouraged to eliminate poisons. Was it any wonder that a man who had sat at a desk in a faulty position for twenty years should suffer from constipation and religious doubts? The osteopath would remove the curve in his back, ease his subconscious mind, and persuade him that he had no use for the surgeon. Osteopathy appealed in all classes. It appealed pre-eminently to theosophists, lawyers, and politicians. Six registered British medical practitioners were practising osteopathy, and nearly 120,000 patients had been treated in this country. Importers from America had founded schools of osteopathy in this country, and had issued diplomas to pupils who were now practising in the Midlands. They held it time that the British public was protected from this. British medical practitioners should be granted a diploma by the British Osteopathic Association after one year's training, for which many were anxious. The British Osteopathic Association was anxious to demand or to

CORRESPONDENCE.

force the General Medical Council to allow anaesthetists to work with registered osteopaths. Think, he said, of the amount of suffering which could be avoided if all school children could have their backbones treated by osteopaths. Only 20 per cent. of children had normal backbones. Orthodox medicine was not a science but a collection of empirical procedures without any underlying principle. Osteopathy was an art with a basic principle. Dr. Drummond Shiels asked whether at the osteopathic school at Kirkcaldy there was nowadays a departure from the principles of osteopathy and a teaching of general surgery. Dr. Macdonald said that was because the State boards insisted on asking questions on general surgery before issuing a certificate. He admitted that the position was similar in this country, but he was asking that the position for a special school of osteopathy might possess valuable recognition for a special school of osteopathy. The osteopaths asked Dr. Graham Little said the country such special knowledge was acquired at the end of a general training. The osteopaths asked them to recognize a short cut. They would command more respect if they recognized that their claim to learn all about the spinal column in four years was absurd. Dr. Salter asked whether cancer, tuberculosis, and small-pox were outside the field of osteopathy, but not cancer. That he sent at once to the surgeon.

Mrs. Hilton Philipson cited the case of a young woman with consumption who went to an osteopath against the advice of her physician, with the result that the lung had been injured and haemorrhage caused. Was that possible? If so, was the osteopath one of the charlatans against whom Dr. Macdonald warned them? Dr. Macdonald answered that such a mishap was possible. He had seen a case.

Another speaker drew attention to the fact that a bill for the registration of medical herbalists had been circulated. Was their registration to be supported by the meeting? Dr. Macdonald replied that they power to sign death certificates. Dr. Macdonald's declaration definitely did not.

Dr. Fremantle called attention to Dr. Macdonald's declaration that framework abnormalities were the basis of ill health. Were that the cause of small-pox and tuberculosis? Dr. Macdonald replied that the tubercle bacillus could not make a start without abnormality of the spinal column. The osteopath worked to improve the blood supply to the affected area. Dr. Fremantle then asked whether histology, physiology, and anatomy were taught to osteopathic students. Dr. Macdonald replied that they were part of the preliminary examination.

Mr. Rosslyn Mitchell suggested that a consultative committee should be appointed so that the members of Parliament participating should not be regarded as pledged to the advocacy of osteopathy. Mr. Mackenzie Livingstone and Mr. Arthur Greenwood were appointed to summon a meeting of all members interested in the subject, who might be present, but did not speak before this Sir Herbert Barker was present, and he briefly declared his interest in the case put forward by the osteopaths.

Correspondence.

THE IMMEDIATE AND REMOTE EFFECTS OF SUNLIGHT.

Sir,—The note of warning sounded by Sir George Lenthal Cheatle (JOURNAL, March 28th, p. 631) with regard to the possibility of harmful effects to the skin from ultra-violet irradiation will, I am sure, find support from all those who are genuinely anxious that this valuable therapeutic aid shall not be brought into discredit by extravagant claims as to the conditions it is likely to benefit.

Unfortunately, when a remedy for certain diseases, however old and well tried, becomes popularized in the lay press the public swings the pendulum too far to the other extreme. Those who have had experience of this treatment know well, not only the possibility of overdose, but also the possibility of harmful exacerbations occurring. Cases of quiescent phthisis have been known to be lighted up in circumstances pointing strongly to the injudicious use of ultra-violet rays, and I have seen a case of arthritis react with a recurrence of acute abdominal symptoms in the region of the appendix which previously had not given trouble for many years.

Two examples of how "fools rush in" will, I hope, give emphasis to Sir Lenthal Cheatle's call for care and judgment, especially when every masseuse and electrical clinician, especially when recommending sun-ray baths for every ailment, are giving or recommending to press upon me a stand with a revolving chair with no less than six tungsten arcs ranged closely round it! And he assured me that "you can easily obtain an erythema dose in three minutes" Sir Henry Gauvain has emphasized again and again that we have no definite or final evidence that bronzing of the skin can be correlated with satisfactory clinical results,

while the danger of overdosage does not seem to have been considered. On another occasion a manufacturer of electrical equipment was approached by a firm of builders to supply ultraviolet are lamps in the bath rooms of some houses that were being erected—I am, etc., C. B. HEALD.

London, W.1, April 2nd.

BACTERIAL VACCINES.

Sir,—May I draw attention to a paper published in the JOURNAL of December 13th last (p. 1103) by Dr. L. S. P. Davidson on the effects of physical and chemical agencies on bacterial vaccines, read at the Annual Meeting of the Association at Bradford?

The opening statement reads: "For some considerable time it has been my opinion that physical and chemical agencies when applied to a vaccine would result in a great part of its antigenic value being lost." He next refers to his earlier experiments upon rabbits with typhoid vaccine emulsion and "detoxicated" typhoid vaccine, and states that he immunized rabbits with the former and inoculated rabbits with the latter, but on subsequently testing the serums of the six animals by the agglutination and complement fixation tests comes to the conclusion that, "as evidenced by the antibody response to the different antigens, very marked diminution in antigenic value was noted in the case of the detoxicated vaccine." The presumption is that he regards agglutination and complement fixation as evidence of formation of antibody, and in the remainder of his most interesting paper—which affords much food for thought—he develops the theme by means of a series of experiments in which *B. tuberculosis*, *B. suis*, *pestifer*, and the pneumococci are employed.

The author's conclusions bear out his opening statement. He says:

"(1) As shown by *in vitro* immunity reactions, the antigenic values of detoxicated and defatted vaccines are in no way comparable with those of the ordinary heat-killed bacillary emulsions in saline. (2) It would therefore appear that the physical and chemical processes involved in the preparation of the detoxicated and defatted vaccines are responsible for the marked loss of antigenic value."

I trust he will continue his experiments, and in doing so will take account of the experience of two workers, S. Rowland and A. S. Leyton (Grünbaum)—both now passed away—with whom I had the privilege of some association. I refer particularly to Rowland's work on the plague bacillus, for it was from a growth of this organism that he isolated a toxic nucleo-protein with which he immunized horses and so obtained a serum showing marked curative and protective properties when administered to rats infected by the same strain of organism.

With reference to the interpretation of Leyton's phenomenon of specific agglutination, I can confirm unreservedly that even under the stringent conditions with which he surrounded this test—namely, microscopic observation only, a definite degree of serum dilution, a stated and limited period of observation, a definite stage of the illness for making the test—he always recognized the possibility of so large an error as 1 in 8, so far as the typhoid group of infections is concerned. At no time did he consider the agglutination method other than of application in diagnosis only, to be read generally in conjunction with clinical findings. I never heard him state otherwise than that as the outcome of many years' observations his conviction remained that agglutination bore no relation to immunity. Notwithstanding the large possibility of error when applied to isolated cases, no one can doubt the exceeding value of his agglutination test when applied to a series of cases in presence of an outbreak—and this is the recognized upper limit of its value.

Dr. Davidson, in his experiments upon rabbits infected with the *B. suis* *pestifer*, confirms observations of previous workers as to failure to protect against a fatal dose when the animals, previously prepared by varying vaccines, detoxicated and otherwise, are subsequently given an ascertained minimum lethal dose of the living organism, with the result that practically all the "prepared" animals

<sup>1</sup> Rowland's publications upon this and cognate subjects appear in the *Journal of Hygiene*, vol. xi, December, 1911, pp. 11 et seq., and in the *Plague Supplement*, Nos. III and IV, vol. xiii (1914) and vol. xiv (1915) respectively.

succumbed. His final statement leaves much room for thought:

"The conclusion to be drawn from this protection experiment is that the virulence of the test culture was of such high grade that the increased resistance produced by vaccine immunization was still insufficient to protect these animals from lethal doses."

He is here evidently wedded to the view that certain serological phenomena—namely, agglutination and complement fixation—are terms interchangeable with increase of natural immunity. Yet all his experiments are directly to the contrary.

I trust he will bring forward fresh evidence in support of his views, for many practitioners, including myself, are by no means happy upon the subject, and we would like more enlightenment. This matter has much too important a bearing on clinical medicine to be disposed of by generalizations based on somewhat narrow laboratory tests involving misinterpretation and misapplication of fundamental phenomena whose value and limitations have been recognized and confirmed by many clinical workers. Detoxicated and other vaccines are now undergoing extensive clinical trials; as matters stand, time alone will tell which of the preparations are likely to survive.—I am, etc.,

MYER COPLAND.

London, N.W.4, March 23rd.

### THE PAINFUL DYSPESIAS.

SIR,—In your issue of March 21st (p. 556), in the report of a recent meeting of the Brighton and Sussex Medical-Chirurgical Society, there are a few lines on my remarks during the discussion on Mr. Fletcher's paper. As these stand they are calculated to give a somewhat erroneous idea of my meaning, and therefore I hope you will allow me now to try to correct any such false impression. It is, I know, very easy for a few unprepared remarks to be misinterpreted.

What I wished to convey was this—that too much must not be expected of the mere black and white evidence of an x-ray photograph (or series of photographs) *per se*; and that, in most cases, everything depends upon the capacity of the radiologist making the examination, and his ability to interpret what he sees. The screen examination in a gastric or duodenal case is much more important than any photograph, or series of photographs. The x-ray evidence obtained must be taken in conjunction with the clinical evidence, and the diagnosis arrived at by carefully considering both.

I am a firm believer in the great value of x-ray evidence in these gastric and intestinal cases, and think that there are very few of them in which we can afford to do without it. The x-ray investigation is as important as any other method, and of more value than some. It is very often the deciding factor in arriving at a diagnosis. The trouble is that it is frequently used in much too loose a way, and, as I said before, too much is often expected of black and white evidence *per se*; x-ray investigations of these cases—just like ordinary clinical investigations—depend for their value upon the capacity and intelligence of the man who carries them out.

In speaking of gastric carcinoma, my chief object was to point out the value of x-rays in the general diagnosis of these cases, and not only to lay stress on the special point of their value in deciding the possibility of operation. It has been stated that, at the Mayo Clinic, 95 per cent. of cases of gastric carcinoma have been diagnosed by x-rays.—I am, etc.,

W. BARRINGTON PROWSE,  
Honorary Radiologist, Sussex County Hospital.

Brighton, March 22nd.

### RESPIRATORY ORTHOPAEDICS.

SIR,—I am gratified to learn from the letter of Mr. Alan H. Todd (March 28th, p. 635) that the orthopaedic specialist is actively interested in the difficult problem of the adenoid child, for it is to him that we must look for help in certain aspects of it. How difficult that problem is, and how deeply the whole question of national health is involved therein, can be fully realized only by those who have to deal with it practically.

Upon the otological side the great advances of quite recent years (I need only mention the perfection of the modern tonsil and adenoid technique, or the splendid work of Friel on zinc ionization in tympanic disease) are sufficient to keep alive the hope that the school otologist will yet rid the world of all the dreadful consequences of middle-ear disease. We are accustomed to look upon the surgery of the temporal bone, with its wonderful elaborations and extensions, as one of the triumphs of modern medicine, and those of us who practise it are very rightly and properly proud of whatever degree of skill we may individually possess. But the school otologist must in a special degree look upon his most successful case of the kind as a compromise at the best, for the very reason of his existence is that he may render major operations unnecessary. I have for many years believed, and never tire of preaching to the few who will listen, that when the importance of the adenoid problem is universally realized the surgery of the temporal bone will always begin, and usually end, in the nasopharynx.

There is no advance in the treatment of the respiratory complications which can be in any way compared to the otological; mainly, it is to be supposed, because we have in the respiratory mechanism of the adenoid child a problem which is as yet unsolved. It is commonly held, for example, and I believe taught by authority, that the insufficient aeration of the blood and the thoracic deformity of the adenoid child are due to his being unable to take in enough air because of the mechanical obstruction by the growth. That cannot be the explanation in the many cases with bad adenoids without enlargement of the faucial tonsils. There is in these no mechanical obstruction between the outer air and the glottis; and, the mouth being wider than the nares, it would be possible to inspire through it a correspondingly greater volume of air but for the presence of some factor of deeper physiological significance than mechanical obstruction of the posterior nares. The position of expiration which the thoracic structures of the adenoid child tend always to assume can be explained only by the recognition of this further factor, which is reflex stimulation.

1. The presence of the adenoid growth in the nasopharynx sends constant expiratory stimuli to the respiratory centre in the medulla through the glosso-pharyngeal nerve.

2. The inspiration of raw air by the mouth irritates the sensory nerve of the larynx (the superior laryngeal). The purely expiratory nature of this stimulation reinforces the expiratory reflexes from the nasopharynx through the glosso-pharyngeal.

3. Such irritation of the superior laryngeal nerve, a constant factor in every case, is a vagal stimulation which, by decreasing the calibre of the bronchioles, furthermore increases the resistance to the inspired current.

The effects of these constant impulses to expiration are seen in the resultant deformity of the thoracic cage with all its associated disasters. In the course of a very short time there is established an abnormal respiratory rhythm, which is not greatly influenced by the mere surgical removal of the naso-pharyngeal growth which initiated it. Operation certainly provides an airway through which the child can breathe if he will, but, as Mr. Todd so truly says, "usually he does not will." The adenoid subject never takes a deep breath—partly because he is too engrossed in the child's subjective world of reverie and make-believe to overcome a physical deficiency by an act of will (that is to say, he cannot be bothered), but chiefly because even such shallow diaphragm-breathing as he has become accustomed to is a constant struggle against reflex expiratory impulses and the resulting thoracic disability.

Respiratory exercises for the correction of abnormal rhythm are useless unless scientifically devised so as to be applicable in their different forms to the several varieties of disability. The form of exercise which improves or cures a case of faulty breathing with a mobile thorax is useless or actually harmful where there is shallow diaphragm-breathing with rigid thorax and a dilated right heart.—I am, etc.,

OBITUARY.

Obituary.

DISEASE AND HABITS OF INTemperance.

Sir,—I enclose a rather entertaining card. Great capital is being made here [Breslau, Germany] by those interested in liquor out of figures purporting to be based on statistics compiled for the British Medical Association. Some of the professors here would like to be able to refute these figures if they have been falsified. I should be exceedingly grateful if you would very kindly inform me (1) if these figures accurately represent the result of the statistics, and (2) where I can find an account of the methods employed in the investigation.—I am, etc.,  
W. N. GOLDSCHMIDT, M.R.C.P.Lond.

(Dated) Breslau, March 21st.

••The figures alluded to are taken from the report of the Collective Investigation Committee on the Connexion of Disease with Habits of Intemperance. It was published in the BRITISH MEDICAL JOURNAL of June 23rd, 1888, where it filled twelve pages. It was compiled by Dr. (now Sir) Isambard Owen, who acted as secretary of the committee. We referred the above letter to him and he has been good enough to send the following note:

The inquiry reported on was not primarily concerned with vital statistics, though some interesting information bearing on the subject was incidentally obtained. Its object was to ascertain what particular forms of disease were especially attributable to alcoholic excess. The table quoted was followed in the report by a statement that the figure for the total abstainers was presumably greatly influenced by the low average age of then living total abstainers as compared with that of the other classes, the ranks of abstainers having been recently largely recruited by propaganda among the young. This was further shown by additional calculations to have been actually the case. The final conclusion on this point was that "We have not in these returns the means of coming to any conclusion as to the relative duration of life of total abstainers and habitually temperate drinkers of alcoholic liquors."

An enterprising journalist communicated the table to the lay press, suppressing the context and announcing the bare figures as the "conclusions" of the British Medical Association. No great harm would have been done by this, had not a certain number of zealots for total abstinence, men into the trap, and, without taking the trouble to verify the accuracy of the newspaper paragraphs, incautiously rushed into print to combat these imaginary "conclusions" by wholesale charges of incompetence, bias, and so forth, against everybody concerned with the report. This brought the liquor trade into the field, and the supposed "conclusions" were soon transferred to large posters and displayed in a number of public houses and bars in various parts of the Kingdom.

I wrote at that time some two hundred letters to the press to warn the public against these notices and similar statements, and was backed up by the then ablest advocate of total abstinence—the late Dr. Norman Kerr. The notices disappeared, but some germs of the malady seem to have survived to cause an occasional sporadic outbreak.

RADIUM EMANATION (RADON).

Sir,—In reply to the letter of Mr. Hayward Pinch in your issue of April 4th (p. 681), the Radium Committee of the Middlesex Hospital does not hold itself responsible for certain unjustifiable claims which have appeared in the press respecting the new Radon Centre at the Middlesex Hospital. This centre has been established at the request of the Medical Research Council, and with the financial support of the British Empire Cancer Campaign, to enable a wider research to be made into the uses of radium emanation. The services of the new installation will not be restricted to the Middlesex Hospital, but will be available for certain other hospitals.

The Middlesex Hospital has always recognized the valuable pioneer work of other centres in the use of emanation in this country, and has already in the lay press disclaimed priority in this field.—I am, etc.,  
W. SAMPPSON HANDLEY,  
Chairman of the Radium Committee of the Middlesex Hospital.

April 6th.

ABRAHAM EMRYS JONES, M.D.  
Dr. ABRAHAM EMRYS JONES, who died at his residence in Manchester on March 31st, was born in 1852 at Llanarth, Cardiganshire. His early education was received at Cardigan Grammar School, and later at a school at Frome in Somerset. He left school at the age of 16, and developed an active interest in politics. Later, however, he turned to medicine, and after studying in Glasgow graduated M.B., C.M., and L.M. at the University of Edinburgh in 1875. In the following year he obtained the diploma of Membership of the Royal College of Surgeons of England. In 1877, for a thesis on work connected with the eye, he received the degree of M.D. Edin. with special commendation. In 1875 he held the appointment of resident surgeon officer to the Hulme Dispensary, Manchester, and shortly afterwards was appointed house-surgeon to the Manchester Royal Eye Hospital, becoming honorary assistant surgeon to that hospital in 1879. He held numerous other appointments during his active career, including those of consulting ophthalmic surgeon to the Bolton Infirmary, the Jubilee ing ophthalmic surgeon to the Bolton Infirmary, the Jubilee oculist to the Barnes Home Industrial Schools, the Jubilee Schools, and the Warehousemen and Clerks' Schools. In addition he was a medical referee under the Workmen's Compensation Act for injuries to the eye. He contributed a number of papers to medical literature on ophthalmic subjects. From time to time he delivered a series of lectures and discourses on various subjects, and one of his addresses on the disposal of the dead, under the presidency of Cardinal Vaughan, then Bishop of Salford, must be specially mentioned. This lecture led to the erection of the crematorium at Manchester, of which he was a strong supporter. His name will always be associated with many public movements, but owing to his later dislike of politics he never took an active part in municipal affairs, but he was a justice of the peace for the city of Manchester. Politically Dr. Emrys Jones was a liberal. He was patron and president of the Welsh National Society and the Manchester Ophthalmic Society, and of the Medical Board of the University of Wales. In 1911 he was elected president of the Manchester Medical Society; his presidential address was devoted to the life of Lord Lister, and contained many interesting references to his work as a surgeon and a teacher.

During the active part of his career he occupied a prominent position as one of the leading eye specialists in the district. Though he retired from active practice many years ago he still continued to live at his old consulting rooms in St. John Street, and was to be seen almost daily taking his walks in Manchester. His favourite pursuits, apart from his work, were literature and music, and his love of nature and romance was greatly deepened by his Welsh character and temperament. The funeral service was held at the Manchester Crematorium on April 3rd, and was attended by a number of his medical colleagues. Representatives were present from the Manchester Royal Eye Hospital and the Manchester and Salford Sanitary Association.

JAMES E. KELLY, M.D., F.R.C.S.I.,  
New York.

A very original and interesting personality, in the person of James E. Kelly of New York, died in that city on February 28th. He was born at Oakmount, co. Galway, eighty years ago, and studied medicine in Dublin, becoming F.R.C.S.I. and surgeon to the Jervis Street Hospital, where he soon acquired a great reputation as a brilliant and original surgeon, a most attractive and popular lecturer in surgery at the hospital and the Loder Medical School, since merged in the school of the Royal College of Surgeons in Ireland. He was beloved alike by students and patients for his many alluring qualities of head and heart. In 1883 he was established in Dublin as a surgeon of great

eminence, with a very large practice and a brilliant professional future in front of him, contributing arresting articles to the surgical journals and to *Bryant's Surgery*, a standard book of the period. To the amazement of his hosts of friends he suddenly, under the influence of Henry George, decided to leave Dublin and sacrifice his established position because he felt the political atmosphere of Dublin at that time was oppressive to his strong democratic views. He cut his cable and sailed with his young and numerous family—a nineteenth century pilgrim—to Boston; but with a very different political and religious ideal from that of the earlier pilgrims. He became surgeon to the largest hospital in Boston—the Charity. He only spent three years in Boston, as even there he did not find that full democratic freedom which he yearned for. So to New York he migrated, where he practised and flourished for forty years. He was surgeon on the staff of the City, the Gouverneur, and the French Hospitals, professor of anatomy and surgery at the Post-Graduate Medical Society (New York), and founder of the New York Celtic Medical Society. In New York, as in Dublin, he soon established a wonderful reputation for surgical skill of the highest order, great originality, and independence of character that almost verged, in its integrity, on the quixotic; the loss of fees or patients never weighed for a second with J. E. Kelly if any small or big point of principle or professional dignity was at stake. Almost to the last he continued the practice of his profession. He was a man of extraordinary physical and mental energy. Almost daily, through his long years of residence in New York, he went to the New York Athletic Club ground to cycle and box with the well known amateur and professional boxers of the day, and indulged in other athletic pursuits. His activities were numerous and his personality was of arresting interest to all who came within the charmed circle of his friendship. He leaves behind him his widow (formerly Miss Morrough of Dublin), two sons (one a distinguished ophthalmologist in New York), and a married daughter. The outstanding feature of James E. Kelly was his mesmeric personality, his devotion to his profession, with the highest and noblest ideals, his kindness to friends and patients, his loyalty to all.

#### REDMOND ROCHE.

Dr. ALBERT WILLIAM BEAUMONT died at his residence, Oak Hall, East Ham, on March 26th, in his 71st year, after many years of ill health. He was educated at St. John's College, Cambridge, and St. Mary's Hospital, obtaining the diploma of L.S.A. in 1882, the L.R.C.S. Ed. and L.M. in 1885, and graduating M.D. Dubl. in 1898. In 1886 he began to practise in East Ham, and was appointed surgeon to the Gas, Light, and Coke Company's Workmen's Provident Society, holding the post for nearly forty years. For many years he was medical officer of health for East Ham before it became a county borough, resigning subsequently owing to the pressure of private practice. His other appointments included those of medical officer to the East Ham Division of the West Ham Union for over thirty years, and consulting surgeon to the East Ham Cottage Hospital. He was a member of the British Medical Association and a Fellow of the Society of Medical Officers of Health. In 1918 he was joined in partnership by his eldest son, Dr. O. A. Beaumont, who succeeds him in the practice.

Dr. HENRY JOHNSTON BOYD of Hillsborough, co. Down, Northern Ireland, died in a private nursing home in Belfast on March 29th. He had been ailing for some time, and finally sought relief in an operation, but his strength was not equal to the demands made upon it, and he never fully rallied. He took the diplomas of L.R.C.P. and S. Ed. in 1880, and had been forty-one years dispensary medical officer of the Hillsborough district; he was most unremitting, painstaking, and conscientious in the discharge of his duties, beloved by his patients and all who came closely in contact with him, and universally respected and trusted in his area. He was always a member of the various local committees of the British Medical Association, and attended the meetings when his time was not occupied by numerous

other calls. He held a high place in the estimation of his medical brethren, on account both of his professional ability and of his sterling worth, and as one who kept himself acquainted with recent medical advance. He leaves a widow and one son, at present assistant tuberculosis officer for County Down; with them much sympathy is felt.

Professor RUDOLF THIES SOEN, director of the Freiburg University Surgical Clinic, has recently died of pulmonary embolism following fracture of the femur, at the age of 41. A memoir of him appears in the *Zentralblatt für Chirurgie* of March 28th.

Dr. LEO TESTUT, the well known professor of anatomy in the Lyons Faculty of Medicine, has recently died.

## Universities and Colleges.

### UNIVERSITY OF LIVERPOOL.

THE following candidates have passed the examination for the diploma in tropical medicine:

J. Black, E. J. Crawford, Mary W. Ellam, F. N. Green, J. T. Johnson, Elizabeth K. Mackay, K. S. Shah, C. H. B. Thompson, J. J. de Wael.

\* Recommended for the A. H. Milne Medal.

### UNIVERSITY OF ABERDEEN.

A GRADUATION ceremony was held on April 1st, when the degree of M.D. was conferred upon four successful candidates and those of M.B., Ch.B. upon fifty-one candidates; the names were printed in our issue of April 4th (p. 682).

The diploma in public health was conferred upon the following successful candidates: Agnes M. E. Benzie, J. C. Kerrin, Christina R. Laing, J. C. Milne, Lily M. Watt, Mabel Wilson.

### QUEEN'S UNIVERSITY, BELFAST.

THE special spring graduation ceremony of the Queen's University, Belfast, was held on March 31st, when the following degrees and diplomas were conferred:

M.D. (with commendation).—Edward Armstrong.

M.B., B. Ch., B.A.O.—Rachel A. Elliott, R. J. C. Maxwell, Margaret Bamber, D. D. Barker, Norah E. Bingham, Rabie A. Browne, N. C. Burns, W. M. Burns, R. J. W. Burrell, J. E. Campbell, Kathleen Cathcart, Charlotte C. Carlisle, P. H. Deeny, D. S. Gordon, P. Higgins, F. V. Hill, R. S. Johnston, J. A. Kelly, C. A. Keph, M. C. MacCormac, J. McGeough, C. Macready, T. A. Muckle, W. C. S. Murray, J. Purce, S. Robinson, G. Scarlett, Jane S. Walker, Margaret Young.

D.P.H.—J. Patton.

\* With second-class honours.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

#### RE-ELECTION OF PRESIDENT.

AN extraordinary Comitia of the Royal College of Physicians of London was held on Monday, April 6th, at 5 p.m., the President, Sir Humphry Rolleston, being in the chair.

He referred to the loss the College had sustained by the recent death of the Registrar, Dr. J. A. Ormerod, and, on the motion of the Second Censor, a resolution expressing condolence with his family and referring to his services in the office of Registrar for more than sixteen years was passed in silence, all the Fellows standing.

The President then delivered the annual presidential address. He referred to the fact that there are now 373 Fellows as against 91 a hundred years ago, and that the Members now numbered 688, while there was still one Extra-licentiate. He referred to the work of the College during the past year, mentioning the special alteration of the by-laws, permitting the admission of women to the Fellowship. He then delivered obituary addresses upon the eleven Fellows who had died during the presidential year—namely, Dr. Hugh Walsham, Dr. R. Hingston Fox, Sir Sydney Russell-Wells, Dr. Sidney H. C. Martin, Dr. Henry Gervis, Dr. J. F. W. Tatham, Dr. Herbert Williamson, Dr. Clement Dukes, Sir James Mackenzie, the Right Hon. Sir Clifford Allbutt, and Dr. J. A. Ormerod.

On the motion of the Senior Fellow, Sir William Church, a hearty vote of thanks was accorded to the President for his address. Sir Humphry Rolleston vacated the presidential chair and the College proceeded to the election of President. Sir Humphry Rolleston obtained 83 votes out of 94 voting, and was re-elected President for the ensuing year.

Licences were granted to four candidates, and permission given to seal their diplomas. Communications were received from the Secretary of the Royal College of Surgeons, dated February 13th and March 12th. The meeting was then constituted as a special extraordinary Comitia for the purposes of a report from the Censors' Board. This report having been adopted, the following resolution was passed on the motion of the Senior Censor:

"That William Lovell be declared to be no longer a Licentiate of the College; that he forfeit all the rights and privileges of a Licentiate; and that his name be expunged from the List of Licentiates during the pleasure of the College."

The President afterwards dissolved the Comitia.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council meeting was held on April 2nd, when the President, Sir John Bland-Sutton, was in the chair.

## Election of Fellows.

The following Members of twenty years' standing were elected Fellows: Dr. Alexander Primrose, C.B., Professor of Clinical Surgery in the University of Toronto; and Mr. J. Basil Hall, M.Chir. Cantab., Consulting Surgeon, Bradford Royal Infirmary, President of the British Medical Association.

## Diplomas and Licence.

Diplomas of membership were granted to two candidates. The licence in dental surgery was granted to one candidate.

## Jacksonian Prize.

The Jacksonian Prize for 1924 was awarded to Mr. A. Lawrence Abel, the subject for that year being "The pathology, diagnosis, and treatment of oesophageal obstruction." A certificate of honourable mention and an honorarium were awarded to Mr. E. Musgrave Woodman for his dissertation on this subject. The subject for the Jacksonian Prize for 1925 will be "The pathology, diagnosis, and treatment of abscess of the brain."

## ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly meeting of the President and Fellows, held on April 3rd, Francis Joseph O'Donnell, L.R.C.P. and S.I., M.R.C.P.I., was elected a Fellow of the College.

The following were admitted as licentiates in medicine and midwifery:

Anna M. Allen, M. J. Cleary, R. F. G. Dickson, J. A. Donworth, W. J. Finnerty, C. Gardner, J. Graff, T. Griffith, D. J. Keane, M. J. Kelly, T. R. McCabe, M. A. Monahan, Aileen M. Mulcahy, M. O'Regan, B. Plunkett.

## The Services.

## AUXILIARY R.A.M.C. FUNDS.

THE annual meeting of the members of the Auxiliary Royal Army Medical Corps Funds will be held at 2.30 p.m. on Friday, April 24th, at 11, Chandos Street, London, W.1, when the annual report and financial statement for the year ended December 31st, 1924, will be presented, and the officers and committee for the current year elected.

## Medical News.

DURING the last three weeks the number of deaths ascribed to influenza in the great towns of England and Wales has not varied much; the figures were 283, 304, 278. The numbers of cases of pneumonia (primary) notified in England and Wales have followed a similar course (1,395, 1,523, 1,418). In the South the stress of the epidemic seems to be past, but in the Birmingham district the mortality is still high. Last week Birmingham recorded 34 deaths, the same number as in the previous week. The only London, with 26 deaths) which returned Trent (15), Liverpool (15),

A COURSE of lectures and demonstrations will be given at the General Hospital, and at the Queen's Hospital, Birmingham, on April 21st and Fridays from 3.30 to 5 p.m., commencing on April 21st and May 1st respectively. The course, which includes demonstrations on medical and surgical cases, skin diseases, ophthalmic cases, children's diseases, urinary diseases, insulin treatment, etc., will be given by the medical and surgical staffs. One demonstration will be given at the Children's Hospital, Ladywood Road, Birmingham. The fee for the course is 1 guinea. Further particulars can be obtained on application to the hospitals.

THE Fellowship of Medicine announces an intensive course in medicine, surgery, and the special departments, beginning on April 20th at the Hampstead General Hospital. From April 20th to May 2nd a course in proctology will be held at St. Mark's Hospital, and a special course in diseases of children at the Queen's Hospital, Hackney Road. In May courses will be given in dermatology at the Hospital for Diseases of the Skin, Blackfriars; in diseases of infants, at the Infants Hospital; in diseases of the throat, nose, and ear, at the Central London Throat, Nose, and Ear Hospital; and in psychological medicine, at the Maudsley Hospital. Copies of the syllabus of these courses may be obtained from the Secretary to the Fellowship of Medicine, No. 1, Wimpole Street, W.1.

On April 1st Lord Balfour opened the new Hebrew University of Jerusalem, the organization of which was described in our issue of March 7th (p. 471). In his speech Lord Balfour pointed out that the Hebrew language, associated in the past with the poetry and religious teaching of

Isaiah, was capable of being used in such modern extensions of science as microbiology. Three great theories in science—those of creative evolution, the new psychology, and relativity—had been enunciated by Jewish investigators, and in the darkest days of the Middle Ages Jews and Arabs had combined to provide the first sparks which had led eventually to the scientific illumination of Europe. The British Medical Association was represented by Wing Commander W. Tyrrell, D.S.O., M.C., R.A.F.M.S., Principal Medical Officer of the Palestine Command.

THE KING has approved the award of a Royal medal—the Patron's Medal—by the Royal Geographical Society to Dr. A. F. R. Wollaston, D.S.O., for his explorations and journeys in Dutch New Guinea, Central Africa, and many other parts of the world. Dr. Wollaston was medical officer and naturalist to the first Mount Everest Expedition in 1921.

THE Kensington Division of the British Medical Association is arranging a ball in aid of the Royal Medical Benevolent Fund and Guild, to be held at the Kensington Town Hall, on Thursday, May 7th, from 9 to 2 o'clock. Corelli Windeatt's band has been engaged. Tickets, 1 guinea each, or six for 5 guineas, can be obtained from the Honorary Secretary, Dr. Howard Stratford, 20, Upper Phillimore Place, Kensington. As a result of last year's dance the Division was able to hand over £125 to the Fund after all expenses had been paid.

THE annual meeting of the Medical Missions Department of the Society for the Propagation of the Gospel in Foreign Parts will be held at 8 p.m. on April 22nd, in the Great Hall of the Church House, Westminster. The chairman will be the Bishop of Singapore, and the principal speaker will be Dr. F. S. Drowe, from Holy Cross Hospital, East Pondoland, who will show some new and beautiful slides of his medical work there.

THE report presented to the annual meeting of the Hospital Saturday Fund on April 4th showed that the total receipts for the year had been £107,342, while the total sum awarded was £76,488; the management expenses of the fund were £9,406, or 8.75 per cent. of the gross receipts.

AT the recent annual meeting of the British Spa Federation, which includes the New Zealand spas, certain conditions of membership were laid down. They include the possession of natural mineral waters of approved therapeutic value and of a bathing or pump-room establishment approved by the Federation, and also the existence of suitable local medical authority devoted to spa practice. Treatment must be given only under medical prescription. The amenities and sanitary conditions of the spa must be approved by the Federation, and the spa must be controlled by a public body or an approved private body. Before admitting a spa the Federation will depute three representatives (one of whom shall be a spa medical practitioner) to visit the spa and report fully thereon. Mr. John Hatton, Director of the Baths at Bath, was elected honorary secretary of the Federation to fill the vacancy caused by the resignation of Mr. F. J. C. Broome of Harrogate.

An obituary notice of Sir Clifford Allbutt, with an excellent portrait, appears in *Il Policlinico* (Sezione Pratica) of March 30th.

THE Ministry of Health has issued a *Memorandum* on the duties of medical officers of health in England and Wales. It consists of an introduction and two appendices, the second being "an index to the statutes, orders, regulations, etc., relating to the powers and duties of the medical officer of health." This second appendix is a formidable list, and shows the multiplicity and complexity of his duties. The memorandum can be obtained from the Stationery Office, price 2d. net.

THE University Press announces for early publication a collection of papers written by the late Sir German Sims Woodhead, the late Sir Clifford Allbutt, and Dr. P. C. Varrier-Jones, as the result of experience gained at the settlement for consumptives at Papworth, Cambridgeshire. The volume, to which Sir James Kingston Fowler has contributed an introduction, has been printed at the Papworth Press.

THE late Dr. E. E. Klein, F.R.S., formerly lecturer on advanced bacteriology at St. Bartholomew's Hospital Medical School, who died in February last, aged 80, has left estate of the gross value of £14,598.

MR. E. TUDOR OWEN, O.B.E., has been appointed an assistant secretary of the Ministry of Health.

THE thirty-eighth French congress of ophthalmology will be held at Bordeaux on infantile glaucoma. Further information can be obtained from the general secretary, Dr. René Oufroy, 6, Avenue de la Motte-Picquet, Paris, VII<sup>e</sup>.

THE fourth International Medical Congress of Industrial Accidents and Diseases will meet at Amsterdam from September 7th to 12th. The honorary president is the Minister of the Netherlands to England, Joulkeer Dr. R. de Marees van Swinderen. Apart from the scientific proceedings there will be receptions by the County Council of Amsterdam and the Minister of Labour at the Hague and a trip to the harbours and the surrounding country. The president of the Congress is Sir Thomas Oliver and the honorary secretary Dr. Herman S. N. Menko, 2, Grosvenor Gardens, Cricklewood, N.W.2.

A SET of tables for computing standard metabolism by means of Krogh's respiration apparatus has been published in a small pamphlet by J. H. Schultz, publisher, of 15, Haynagade, Copenhagen. The price is Kr. 1.50.

A COMMITTEE has been formed for the erection of a monument to the Italian physiologist, Angelo Mosso, in his native town of Chiari.

DR. W. W. Keen of Philadelphia and Professor Sanarelli of Rome have been elected honorary foreign members of the Royal Academy of Medicine of Belgium.

DR. TERRIEN has been appointed professor of clinical ophthalmology in the Paris Faculty of Medicine, and Dr. Duvergy professor of urinary diseases in the Bordeaux Faculty.

THE Italian Antituberculosis Congress will be held at Naples from May 25th to 28th, under the presidency of Professor Andrea Fernanini.

## Letters, Notes, and Answers.

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2630 (Internal Exchange). The telegraphic addresses are:

EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology Westrand, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westrand, London.

MEDICAL SECRETARY, Mediscera Westrand, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Draculus, Dublin*; telephone: 4751 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### INCOME TAX. Motor Car Transaction.

"W. A. W." bought in 1922 a B. car for £414, sold it in 1924 for £175, and bought a C. car for £355. The inspector of taxes refuses to allow the net cost, £355-£175=£180, saying that the maximum amount allowable is the excess over £175 of the cost of a car exactly similar to the B., now being sold at £320, instead of at the former £414.

The inspector's contention is unusual and would not, we believe, be supported on appeal. The statutory provision dealing with the question of capital is No. 3 (f) of the rules applicable to Cases I and II, Schedule D, which reads as follows: "Any capital expended or intended to be expended as capital in respect of any trade, profession . . ." shall not be allowed as a deduction. Was any portion of the net £180 expended "capital expenditure"? We think not. "W. A. W." had sunk £414 in equipping himself with a motor car, and for income tax purposes he is not entitled to any depreciation. For such purposes therefore it must be assumed that at the time when the transaction in question took place that was still the amount of capital in the equipment. The contention of the inspector is, in effect, that the transaction added £45 to the capital, which, taking all the circumstances into account, seems to be capable of refutation on the face of it. We suggest that our correspondent should put this argument to the inspector, intimating that he is advised that he would have a good prospect of succeeding in an appeal to the General or Special Commissioners.

## LETTERS, NOTES, ETC.

### THE SUNLESS WINTER.

THE records made at the Agricultural Experimental Station, Rothamsted, Herts., confirm the general impression that the winter of 1924-25 was, if the past tense can be used, uncommonly wet and sunless. For the six months—September 1st to February 28th, which is reckoned the first half of the harvest year, the amount of rain was 20.83 inches, an excess of 5.83 inches. There was practically no extra evaporation from the soil and almost

the whole of the excess of rain drained through it; the amount was 16.029 inches, or 5.749 inches above the average. The average amount of moisture lost by evaporation during the six cold months should be about 5 inches; last winter it was only 4. The annual average amount of sunlight daily should be 2 1/2 hours; it was 2 1/2, and the total amount of sunshine for the six months was 92.2 hours below the average; only January received over the average amount, and then it was only one hour. Though March was dry, the rainfall being 0.781, as compared with 1.219, the amount of sunshine was below the average. No month since last July has been unusually sunny, and so far the hope of Dr. Christmas, of the Records Department, that the spring allowance will be more liberal, has not been fulfilled.

### MATERNAL MORTALITY.

MR. ALECK BOURNE, F.R.C.S. (London), writes: If "A Country Practitioner" (JOURNAL, March 21st, p. 586) and "A Town Practitioner" (April 4th, p. 634), who believe that maternal mortality is "grossly exaggerated," wish to know the cold facts of the situation, they should read the very lucid report on this subject written by Dr. Janet Campbell and published by the Ministry of Health in 1921. There they will see that the death rate per 1,000 births in 1922 was 3.81, of which 1.33 were due to sepsis and 2.43 to "other causes." Compared with some other European countries, the mortality per 1,000 for the years 1911-13 was as follows: Scotland 5.7, France 4.78, England and Wales 3.91, Norway 2.90, Italy 2.44, and Holland 2.29. Spain and Switzerland both had higher rates than England and Wales, but the position of Scotland, as head of the list, and England and Wales, more than half-way up, cannot be any reason for complacency. The distribution of mortality in this country is highest on the whole for rural areas—thus, Breconshire (1919-22) reported 7.88 per 1,000 and Westmorland 6.75, while the average for all the rural districts was 4.22, as opposed to 2.98 for London (1921). It is quite true that many men will have conducted large obstetric practices for many years without a death, but their happy experience is not a true reflex of the condition as a whole. The death rate of a large maternity hospital is inevitably higher than that of any single general practice, but, after all, the death rate in hospitals occurs almost solely amongst the women who are not somebody's practice outside. Having seen the figures, and read the report, it will be for your correspondents to judge for themselves whether there is "gross exaggeration" or too much "fuss" made about a particularly important aspect of public health.

### TREATMENT OF PSORIASIS.

DR. J. B. MACKAY (Alberta, Canada) has sent us a paper on the treatment of psoriasis, from which we extract the following passages:

I believe I have discovered a combined treatment for psoriasis which is not only effective but simple. All possible sources of infection must first be carefully eliminated. I have, rightly or wrongly, traced the original source of the disease in several cases directly to oral sepsis, and I should not expect a satisfactory result until such foci have been removed. The treatment consists of four concurrent procedures, the most important of which is, I think, a series of intramuscular protein injections. Having found it handy and effective, I have used throughout Abbott's "lactigen," commencing with 5 c.c.m. and gradually increasing the subsequent doses to 10 or even 15 c.c.m. The injections are given every three or four days, the rate of increase being determined by the amount of reaction. Usually six injections are sufficient, and, within reasonable limits, the more defulio the reaction is the better are the results. A rise of temperature to 101° or 102° F. during the night following the injection is desirable. An ointment containing chrysarobin is applied daily to each patch (chrysarobin gr. xx, liq. carb. deterg. m. xxx, ung. hydrarg. ammon. chlor. 5 ij, petrolatum ad 3 j). It is essential that this should be rubbed in; any irritation of the surrounding skin can usually be relieved with talcum powder. Once a week a hot bath is taken, after which the exact state of the lesions can be readily seen. Internally thymus gland in 5-grain capsules, three or four times a day, is prescribed. If preferred it may be given by intramuscular injection, or the same effect may be produced by stimulating the thymus with small doses of x-rays, as recommended by Brock (*Muench. med. Woch.*, lxxvii, 191, 1921). Without thymus medication the same steady improvement is not seen; the healing process is more irregular and the results less satisfactory. Lastly, a low protein diet will hasten results; it should be maintained after cure. In my hands the average length of time for the disappearance of all lesions and the return of the skin to normal has been five weeks. The more recent the appearance, or the more "acute" the case, the more speedily it responds; a change can generally be seen within the two days following the first injection, after which the improvement is steadily maintained to ultimate cure. All the amounts stated above refer to adult doses. In my series of cases only one relapsed after treatment; this patient had patches of psoriasis all over the body, and the condition had lasted for many years. Two further injections resulted in cure.

### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 37, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 35 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 172.

APRIL 18, 1925]

THE MORTALITY OF APPENDICITIS.

An Address  
ON  
THE MORTALITY OF APPENDICITIS.  
BY  
JOSEPH E. ADAMS, M.S., F.R.C.S.,  
SURGEON TO ST. THOMAS'S HOSPITAL.

The incidence of a disease and its mortality are the two criteria by which the capacity of the medical profession should be judged. To prevent we must eliminate cause. The cause or causes of appendicitis have been a subject for both speculation and research for more than thirty years, but little has been established beyond the fact that the appendix is a dangerous possession. Its removal is therefore the surest method of preventing appendicitis, and the practice of removing the appendix which is to all appearances healthy, when the abdomen is opened for some other operative procedure, is quite sound provided it does not delay matters and add to the difficulty of the operation in hand. There has been talk of a function for the appendix, but as far as I am aware no one really knows what it is, and, surgically speaking, it is not an organ which it is a nuisance. Unfortunately the risk of having one's operation can never be reduced to that of having one's hair cut, and therefore preventive appendicectomy is customarily limited to those cases where there is evidence of a present or past attack.

Unless an epidemic occurs it is difficult to be dogmatic concerning the incidence of any particular disease. The increase or decrease can be gauged by personal impressions on the part of practitioners, by the collected statistics of institutions, and, lastly, by the returns of the Registrar-General. The last mentioned are certainly the most reliable source of information, but, unfortunately, they deal only with fatal cases. Mortality is not a fair criterion of incidence. If it be accepted that where mortality figures show an increase this must mean a rise in incidence, then much of what I wish to say becomes pointless. The chief value of the Registrar-General's statistics is that they cover the whole of England and Wales, bearing relation to some forty million inhabitants. Institutional figures are not easy to obtain so that they can all be massed in one total, and the impressions of practitioners, so far as I have been able to benefit by them, do not support the view that appendicitis is noticeably on the increase. The question has been carefully studied by Rendle Short.<sup>1</sup> He states that "appendicitis did not become a separately notifiable and recorded cause of death until 1901." This was about the time of King Edward's historic operation for appendicular abscess on the eve of his coronation. The figures Rendle Short quotes end with 1918. His conclusions are important, and those which bear most directly on our subject are as follows:

1. Appendicitis was present, but was relatively rare in this and other countries until the end of the nineteenth century. Since then it has become very common in most highly civilized countries.
2. The rise in Bristol, and probably throughout England, was beginning in 1895, and was pronounced.
3. This rise was most marked at first in towns, in the male sex, and probably amongst the better-off class.
4. The privations of war did not reduce it.

Six years have passed since 1918 and the mortality is certainly higher. In 1918 the number of deaths shown by the figures published by the Registrar-General was 2,416; in 1923 it was 2,826. If the last part of Rendle Short's second paragraph is correct we have ample justification for inquiring why the returns of the Registrar-General show a steady rise in the death rate. I show below the complete figures from 1913 to 1923 inclusive, with their relation to the population (irrespective of sex). I take 1913 because it is a pre-war year, and 1923 because it is the last year available. The figures for the war years refer only to the civil population, and as this meant the

withdrawal of a large number of males from the statistics they are no doubt vitiated.

Year.	Deaths from Appendicitis and Typhlitis. (Registrar-General's Returns.)		Total.	Persons per Million.
	Male.	Female.		
1913	1387	1141	2528	69
1914	1573	1111	2684	71
1915	1441	1062	2503	67
1916	1474	1123	2603	70
1917	1390	1118	2443	67
1918	1298	1151	2418	66
1919	1278	1142	2429	67
1920	1389	1237	2711	72
1921	1474	1211	2735	72
1922	1524	1218	2826	74
1923	1603	1218	2826	74

It may be urged that deaths from peritonitis of unstated origin will show a decrease *pari passu* with the rise in appendicitis deaths. Such, indeed, is the fact, but the total decrease from about 490 to 420 is far too small a figure to afford an adequate explanation for an addition of nearly three hundred deaths from appendicitis. Nor do I think that any satisfaction can be extracted from the variation of the total number of inhabitants of England and Wales. A sufficiently striking contrast is afforded by the difference between the year 1920, when demobilization of the army was completed, and 1923, the respective figures being 67 and 74 deaths per million. These are post-war years, and my own view is that we should be justified in looking for a decrease. Instead there is a rise in these deaths, which most surgeons would be inclined to regard as preventable.

In order to gain further information as to the incidence of the disease I have obtained figures from the leading hospitals and Poor Law institutions in the London district. These should reflect the incidence in the London population, and I have endeavoured to get figures down to the year 1922. The hospital cases show slight diminution since 1912, and the infirmary figures a definite increase. The explanation of this turnover from hospital to infirmary is that the general practitioner, realizing the urgency of cases of appendicitis and the lack of empty beds in the hospitals, prefers to send his cases where he knows they will be admitted without delay. This attitude is, no doubt, correct, and it remains only to demand that the treatment of the infirmary shall be as good as that of the hospital. The mere change of name from "infirmary" to "hospital," which has become the fashion since the war, will not suffice. There must have been a change of spirit and an increased keenness and capacity on the part of the Poor Law medical officers. Such I believe to have been the case, but I regret that these institutions collectively have been unable to supply detailed figures which could be instructively tabulated. The surgical equipment of many of them may well be the envy of the voluntary hospitals, but down to ten years ago this was not the case, and I believe the merits of surgery were largely overlooked by the guardians until the war enlightened them.

Both hospital and infirmary authorities have kindly replied to my inquiry, but the figures obtained are not sufficiently uniform to be massed together. Such figures have little or no bearing on the occurrence of the disease amongst the rural population, as it is recognized that long journeys are forbidden for acute cases, and most country practitioners do not trouble the London hospitals with their appendix cases. So far as the evidence of general practitioners has been available I have not found that it points to any particular increase in either the incidence or the severity of attacks of appendicitis.

MORTALITY.  
At this stage of my argument I propose to leave the statistical method and consider the pathological side of the question. The death rate is certainly proportional to the degree of sepsis present before the case comes under treatment. If an inflamed appendix can drain into the caecum the attack will subside favourably, and this is the state of affairs in catarrhal appendicitis, the mortality of which is nil. If a diseased appendix drains by perforation into the peritoneal cavity the prognosis is grave.

[3355]

\* Delivered in opening a discussion in the Section of Surgery of the Royal Society of Medicine.

A localized abscess may form, and this may be successfully dealt with by Nature or the surgeon. There is little doubt that appendicular pus may be absorbed and disappear without anything more serious than temporary impairment of the patient's health. Appendix abscesses also do burst into the bowel, and if pus is discharged with the faeces the patient may escape the consequences of perforative appendicitis. The two conditions which may precede perforation are ulceration of the wall of the appendix or obstruction of its lumen. In the latter case the tension inside the appendix ultimately becomes so great that it bursts like a distended paper bag, and most surgeons have experienced this during a difficult operation for appendicitis in the obstructed stage. In the former condition local necrosis of the wall, proceeding from mucosa to serosa, occurs without distension. There is no doubt which is the more serious event. The ruptured appendix pours a quantity of infective material into an unprepared peritoneal cavity. The ulcerated appendix is rather comparable to the leaking gastric ulcer. Protective steps on the part of that very useful ally, the omentum, are likely to have been taken, and a perforated appendix is not infrequently rendered almost harmless by being wrapped up in a covering of omentum. The analogy with the large and small gastric perforation is striking. It is rare to find evidence that the omentum has made any attempt to lessen the size of a large perforation of the stomach. Such perforations, on the other hand, are often obscured by reason of the reaction of the omentum, that energetic "plumber" of the peritoneum.

If, then, the mortality of appendicitis is to be abolished by treatment of the disease, sepsis must be eliminated, and the problem becomes one of early diagnosis. This is an ideal which is not likely to be attained, certainly not until it is recognized by the public in general, and mothers in particular, that stomach-ache is not an indication for a dose of castor oil. The mortality of appendicitis ever since it was first classified by the Registrar-General as a cause of death has always been highest between the ages of 5 and 15. This corresponds to the period when the mother is most apt to dose her offspring with aperients, and also that when the doctor finds the interpretation of symptoms extremely difficult. The liability of the doctor only begins with the first consultation, and the treatment of appendicitis is appendicectomy. Medical experience all goes to show that there are two safe periods for operation—one within twenty-four to thirty-six hours of the onset of disease, the other when the inflammation has subsided. With regard to operation in the acute stage, the capacity of the peritoneum is such that although sepsis may be encountered the convalescence of the patient is rarely affected by it. This means that the mortality is little higher than that of the interval operation, which is usually about 3.5 per cent.

#### TREATMENT.

If the incidence has not gone up, why is it that the number of deaths has increased? Can there be anything wrong with our treatment of appendicitis? In his presidential address to the Section of Surgery of the Royal Society of Medicine two years ago Mr. James Berry<sup>2</sup> raised this question. He called attention to the fact that both the public and the medical profession were under the impression that the custom of operating freely for acute appendicitis had resulted in great saving of life. Would that the Registrar-General could support this optimistic view. Mr. Berry hinted that all was not well with the surgery of the appendix, and that greater care was needed in the selection of cases for operation as regards both time and manner. It may therefore not be out of place to review briefly some of the important steps in the history of the treatment.

We start with the beginning of this century. It then required a physician to diagnose the disease and a surgeon to operate on it when required. This plan gave the physician a deal of anxiety and caused the surgeon considerable vexation. Frequently the operator complained that he was not called in soon enough. The physician's attitude gradually underwent a change, and the late Sir William Osler crystallized the position when he wrote in

a late edition of his famous textbook, "There is no medicinal treatment for appendicitis."

There being no scope for drugs, and the diagnosis becoming simple, the physician tended to withdraw from the case. This was the surgeon's opportunity, and the late Edmund Owen, rather more than twelve years ago, was perhaps the most insistent on immediate operation, and immediate appendicectomy, as soon as the diagnosis was made. Postulating that no one could tell the actual condition of the appendix by abdominal examination he made out a strong case, and I think I am right when I say that he carried the bulk of surgical opinion with him. Discussion there certainly was, but the main effect was to enlighten the public and to place the treatment of appendicitis on a firmer surgical footing. The notable achievement was that the practitioner learnt to rush his appendix cases into a surgical home, or hospital, as early in the disease as he could. The Hippocratic facies disappeared, and it did not take long to prove beyond dispute that the mortality for appendicectomy in acute appendicitis when the disease is so limited is very little higher than that for the interval operation.

Sir George Beatson was perhaps Owen's most strenuous opponent, and he advocated a policy of delay. This is in accord with the experience of the American surgeon Ochsner, who since 1892 has practised a policy of delay in appendicular cases. Ochsner maintained that absolute rest in the Fowler position, with only water by the mouth, and the withholding of aperients and morphine, would cause a subsidence of symptoms and an improvement in physical signs in a very short time, even in cases with general peritonitis. That resolution of an inflamed appendix could be confidently expected under this treatment gave the surgeon a new opportunity to practise the art of the physician. Appendicectomy was, and still is, the goal to be aimed at, but the time for the operation is best selected by the operator. It has long been known that the majority of deaths occur amongst cases operated upon from the third to the sixth day of the disease. Therefore if cases can be successfully watched until these days are passed the mortality should be lowered. Many of the cases first seen at this period have an inflammatory mass in the right iliac fossa with little rigidity elsewhere. All such should be classified as having local peritonitis. Some others have general peritonitis. If all these cases are treated by appendicectomy at sight a high mortality must be faced. The patient has already absorbed toxins, and his resistance is an uncertain factor. The disturbance of appendicectomy may just turn the balance of toxic absorption against him before he has had time to develop antibodies and neutralize the toxins present. If all such cases are treated by the Ochsner method, the most favourable result obtainable will be resolution in some and local abscess formation in others. Experience in this country seems to show that there will still be a certain proportion where the symptoms will progress, and because of increasing pain, rising temperature and pulse, and worsened facial aspect, the surgeon will feel impelled to operate. This aspect of treatment has recently been studied by Mr. McNeill Love,<sup>3</sup> and two very interesting papers have been published by him based on the statistics of the London Hospital. He agrees with every other observer that cases operated upon during the first twenty-four hours show a low mortality—namely, 0.9 per cent. The same death rate holds for all cases where the disease is limited to the appendix.

The recognized mortality for the so-called interval operation, where inflammation is presumably in abeyance, is rather less than this—namely, 0.5 per cent. Love presents two tables which give the mortality of acute appendicitis treated by immediate operation and by postponed operation: Operation in both instances means appendicectomy, and immediate operation shows a percentage of deaths as high as 5.8, whereas cases treated on delayed lines are only fatal in 3.5 per cent. These figures are important because the immediate operation cases include a high proportion with general peritonitis—one-seventh of the total—and these have a mortality at the London Hospital of 20 per cent.

Statistical proofs are often looked upon with scorn, but nevertheless a surgeon is influenced by his own statistical results, and it behoves us all to know, and to watch, our

APRIL 18, 1925]

# THE MORTALITY OF APPENDICITIS.

personal figures. For this reason I have prepared, with the aid of Mr. A. C. Halliwell, until recently surgical registrar at St. Thomas's Hospital, and now resident assistant surgeon, figures for the years 1919 to 1923, which may be usefully compared with those published by Mr. Love in the *British Journal of Surgery*. These latter are from the London Hospital, and refer to the years 1920 to 1923.

TABLE I.—Cases Operated on within Twenty-four Hours of Onset.

	London.	St. Thomas's.
Number of cases ...	221	303
Recovered ...	219	296
Died ...	2	7
Mortality per cent. ...	0.9	2.3

TABLE II.—Cases Treated on Delayed Lines.

	London.	St. Thomas's.
Inflammation Subsided:		
Number of cases ...	232	143
Recovered ...	227	143
Died ...	5	0
Mortality per cent. ...	2.1	0.0

Unsuccessfully Delayed:

	London.	St. Thomas's.
Number of cases ...	109	71
Recovered ...	102	62
Died ...	7	9
Mortality per cent. ...	6.4	14.0

Total:

	London.	St. Thomas's.
Number of cases ...	341	214
Recovered ...	329	205
Died ...	12	8
Mortality per cent. ...	3.5	4.2

TABLE III.—Cases in which Immediate Operation was Performed.

	London.	St. Thomas's.
Inflammation limited to the Appendix:		
Number of cases ...	633	348
Recovered ...	627	345
Died ...	6	3
Mortality per cent. ...	0.9	0.8

Local Peritonitis:

	London.	St. Thomas's.
Number of cases ...	467	271
Recovered ...	438	257
Died ...	29	14
Mortality per cent. ...	6.2	5.2

Local Abscess:

	London.	St. Thomas's.
Number of cases ...	347	95
Recovered ...	331	91
Died ...	16	4
Mortality per cent. ...	4.6	4.2

General Peritonitis:

	London.	St. Thomas's.
Number of cases ...	230	187
Recovered ...	185	132
Died ...	47	55
Mortality per cent. ...	20.5	29.4

Total:

	London.	St. Thomas's.
Number of cases ...	1677	901
Recovered ...	1579	825
Died ...	98	76
Mortality per cent. ...	5.8	8.4

TABLE IV.—General Peritonitis Cases. (All treated by immediate operation.)

Day of Attack.	London (230 Cases). Per cent.	St. Thomas's (187 Cases). Per cent.
First ...	6.6	10.6
Second ...	29.8	46.5
Third ...	35.6	21.3
Fourth ...	13.3	9.0
Fifth ...	6.6	5.8
Sixth ...	4.7	1.0
Seventh ...	1.1	3.7

With regard to Table I the higher mortality of the St. Thomas's column may perhaps be excused by the fact that the notes record a rather high proportion of what are called fulminating attacks. Anyhow the figure is higher than it ought to be for such early operation, where the presumption is that the disease is limited to the appendix itself. The last table will show that 10 per cent. of our cases of general peritonitis gave a history of only twenty-four hours, and I shall comment on this later.

Table II seems to show that St. Thomas's has gained the first section the patients it lost in Table I, and I rather think in reading Mr. Love's paper that the operation has been undertaken unduly early, and thus the higher mortality at the London Hospital is accounted for. I think no great clinical acumen is required to recognize that a large number of cases come to hospital with more than twenty-four hours' history, when the attack is obviously subsiding, and these, if sufficient patience is exhibited, will go far to improve

the statistics under this heading. They are cases which without a twenty-four hour rule could be dealt with at once and do no harm to the mortality table. The heading "Unsuccessfully Delayed" is more important, and here I freely admit that our high figure of 14 per cent. is attributable largely to the pernicious system of dual control.

There are one or two points of difference in the practice of the two hospitals to which I should like to draw attention, and I have to thank Mr. Love for information so far as the London Hospital is concerned. In the first place, he tells me that all appendix cases are treated in the surgical wards at that hospital; that many of the surgeons adopt the expectant line of treatment in late cases more or less as a routine. At St. Thomas's Hospital, on the other hand, very little expectant treatment is indulged in on the surgical side, and a large number of appendix cases are still admitted to medical wards. Cases there are seen in the first instance by the resident assistant physician and surgeon, and where the disease appears limited to the appendix or the patient appears to have general peritonitis, immediate operation is arranged for. Where an appendicular mass is diagnosed the case is commonly admitted on the medical side, and here expectant treatment is practised. Dual control I have no hesitation in condemning, and I am convinced that it does not serve the interest of the patient; appendicitis is a surgical disease, and the man who sees and handles the most accurate estimate of the physical signs. A study of the nine fatal cases in our series of seventy-one shows that the mortality was attributable to imperfect appreciation of the degree of infection, and not to the fact that operation was done in the dangerous period of the third to the sixth days. Three of them had general peritonitis when the delayed operation was performed, and an equal number a sub-phreatic abscess, while the remaining three had obstruction of the small bowel.

If we turn now to Table III we shall see that at both hospitals the mortality is weighed down by the cases of general peritonitis. We all know that if our ideals of diagnostic accuracy could be reached the number of these widespread infections would shrink very considerably. General peritonitis is rare with only one day's history, and if we cut out these cases altogether and perform immediate operation on all cases, as shown in Table III, the St. Thomas's mortality comes down to 2.9 per cent. and that of the London to 3.5. These are very respectable figures, and seem to me to justify the gospel I have prepared a fourth table, which deals only with cases of general peritonitis, and shows the day of the disease when they were operated upon in accordance with the principle of immediate attack. It will be obvious that it is the first twenty-four hours which give the diagnostician his chance. It matters not whether he be general practitioner, physician, or surgeon—ho must make up his mind early or the risk to the patient will be increased. It may not matter vastly who does the surgery, but it does matter when the patient first comes under medical observation, and who sees the case. Diagnosis will always be the highest art both in surgery and in medicine, and let us recognize that herein lies the chance of practising preventive surgery, which alone can bring down the mortality of this disease to a level consistent with the pride of our profession.

I think I shall find general agreement when I say that there are three main types of acute appendicitis viewed from the clinical aspect. There is one where the disease is limited to the appendix, characterized by local pain, local tenderness, and usually hyperaesthesia of the skin above Poupart's ligament. To the second variety the old fashioned name of "perityphlitis" might still be applied, for the infection has passed beyond the confines of the appendix, which itself is often gangrenous and usually perforated. The infected peritoneal zone is that of the right iliac fossa or the pelvis. A localized abscess, an inflammatory mass without evidence of pus, or infection ill limited by adhesions, may be in existence at the time the patient is seen. The third main class is that where

there is widespread inflammation, diffuse rigidity of the abdominal wall, very little respiratory excursion, and an anxious expression on the face of the patient. In this last type general peritonitis may be inferred.

If it is true that immediate operation in the first class carries with it a death rate of 1, or less than 1, per cent., I think we shall all agree that we have learnt the correct line of treatment. Personally I do not feel disposed to pay very strict attention to the alleged day of the disease. Appendicitis seldom exhibits the dramatic onset of a gastric perforation, and frequently there is a day or two of ill health before actual pain is felt. I think there may be marked pathological changes in the appendix which cause no pain at all, and they may certainly give rise to no vomiting. If so, the patient may easily be forty-eight hours out in his length of history. If the clinical signs point to appendicitis proper, appendicectomy is the quickest route to restored health. This is in accordance with the view that one can never tell what the diseased appendix will do next.

In the case of general peritonitis I doubt if a policy of "wait and see" has much to recommend it. When it was always thought necessary for a physician to diagnose and a surgeon to operate, some fifteen to twenty years ago, the mortality was 70 per cent. at St. Thomas's. Now it is 29 per cent., and at the London Hospital 20 per cent. These cases still bulk far too largely in our tables, for in the London Hospital cases 13 per cent. of the total treated by immediate operation had general peritonitis, and at St. Thomas's 20 per cent. In spite of this our hospital figures are better than they were fifteen years ago, and I think the credit of this should be given to the improved capacity for diagnosis on the part of the general practitioner, and also to the doctrine of immediate operation for appendicitis. The actual fall in mortality since 1910 for all types of the disease is from 8 to 5 per cent. at St. Thomas's. Another factor, which has perhaps been overlooked, is the abolition of chloroform from operations on septic patients. I say this rather than the introduction of gas and oxygen anaesthesia, because I think that ether is still the anaesthetic most generally used, and when given by the open method it is most satisfactory for the surgeon, and almost anyone can administer it. It is true that cases of general peritonitis under treatment by starvation, the withholding of aperients, and the Fowler position, undergo resolution, or the infection may settle down to a localized abscess, but at present I think we have very few data which will guide us in the selection of such cases if we meet them for the first time with generalized peritoneal involvement.

If, as Mr. Love states, delayed treatment can only be carried out satisfactorily under hospital conditions, are we not in danger of reverting to the old state of affairs? For what the hospitals do to-day the general practitioner will do to-morrow. Let it be admitted that each case presents an individual clinical problem. Is it not so with every disease? But let it be recognized by the public that immediate operation yields the best results in appendicitis and the doctor's duty will be simplified. If we change this point of view the public will get the idea that appendicitis should be treated on medical and not surgical lines, and I think there is a very real danger of the mortality continuing to rise. Public opinion is first trained by the medical profession. Later the same public opinion tends to call the tune for medical treatment. As a proof of this I need only refer to the recent trial of a doctor who failed to take a throat swab in a case of diphtheria and objected to the use of antitoxin. He was prosecuted, not by his medical enemies, but by the Crown for manslaughter. The Crown prosecution was at the instigation of a coroner's jury. Such a power over us does public opinion acquire as the result of education by ourselves. For our peace of mind I think it was a blessing he was acquitted; but the fact that the trial took place shows how careful we must be in formulating rules for public guidance. Patients are less exigent than before the war in demanding the immediate attention of their doctors. Perhaps they are more prone to treat their abdominal pains before summoning assistance. I hope this does not mean that the precious surgical opportunity afforded by

the first twenty-four hours of an attack of appendicitis is often allowed to slip. As long as the ownership of children is vested in the parents I am afraid mothers will continue to misuse aperients, and I am heartily in agreement with Mr. Love when he writes that delayed treatment is hardly to be recommended in the case of young children. Nearly every surgeon, I think, has had bitter experience in this connexion. I would add also that at the other extreme of life, in advanced age, watching and waiting have greater dangers.

It has been advised by some, particularly Sherren, as long ago as 1905,<sup>4</sup> that when cases are seen after the first thirty-six hours of the disease—that is, when the infection is likely to have spread beyond the appendix itself—the tendency should always be towards a policy of delay. Nevertheless he admitted then, and other surgeons have admitted since, that we may regret leaving a case, but we are not likely to regret operating when there is a doubt as to the chance of temporary improvement.

Sherren based his doctrine on the state of cutaneous tenderness present. If superficial tenderness is present in the "appendix triangle," bounded below by Poupart's ligament, above by a line drawn out from the umbilicus, and to the inner side by a vertical line just to the right of the mid-line, it usually means that the appendix is distended and intact. In cases that are subsiding the area becomes smaller and smaller. Disappearance of tenderness without signs of improvement of the patient means serious mischief in the appendix. This latter is a call for immediate operation irrespective of the disease. The presence of cutaneous hyperaesthesia, however, is not a proof of safety, since the infection may spread outside the appendix without leading to any loss of tension within its lumen.

The important discussion, I think, centres around the proper treatment of those cases which I have included in the second clinical type. The disease is no longer limited to the appendix, but as far as the clinical signs are capable of interpretation the name of general peritonitis is not justified. There may be an inflammatory mass, there may be a visible tumour in the right iliac fossa, there may be pus in the pelvis. The day of the disease may be anything from the third to the fourteenth. Cutaneous hyperaesthesia may be present, though usually it has disappeared. What is the proper treatment, viewed in the light of our knowledge of the mortality statistics? Love says that if you practise the delayed operation and choose your cases aright you may expect a mortality as low as 2.1 per cent. If, however, you plan your operation in the future and are compelled to do it in the present, the mortality in unsuccessfully delayed cases will be 6.4 per cent. If you perform immediate operation on cases with local peritonitis or local abscess, the mortality you may expect is 5.52 per cent. He puts together the first two figures and gets the more favourable result of 3.5 per cent. mortality for all cases treated on delayed lines, but I suggest that this includes a large proportion of cases where the condition is obviously subsiding. I do not feel disposed to quarrel with these figures, but I would suggest that it is still good surgery to drain local abscesses rather than to trust to Nature to absorb or discharge the pus.

With regard to the absorption of pus in the peritoneal cavity, I think a note of caution must be sounded. It is true that it can be absorbed, and actual pus may thus disappear, and in due time render the operation of appendicectomy easy; but is it certain that the patient may not suffer in the process? A recent unpleasant experience makes me hesitate to subscribe to this as an ideal process. A previously healthy man was admitted to a medical ward with what was diagnosed as an appendix abscess. His fever lasted only a few days, and in about a fortnight the mass had subsided. He convalesced satisfactorily, and was discharged from the medical ward with instructions to return on the surgical side for appendicectomy. This he did, and the operation was done without any undue difficulty, no pus being encountered. All went well until the tenth or twelfth day, when his heart suddenly began to fail and he died within twenty-four hours. All that the post-mortem examination revealed was a fatty and degenerate heart muscle. Personally I am inclined to

# APPENDICITIS.

APRIL 18, 1925]

attribute this to the toxins absorbed from his abscess. It is one thing for the peritoneum to absorb pus; it is quite another matter for the system to absorb toxins. Relief of tension is the best method of prevention, and I believe that this unfortunate event would not have occurred if the abscess in the first instance had been surgically drained.

In doubtful cases, where the presence of pus is uncertain but there is an inflammatory mass, there is much to be said for the operation of coeliostomy. Drainage, preferably with corrugated rubber, may with advantage be made down to the appendicular lump, and discharge, or resolution, hastened in this way. Immediate operation should not always mean immediate appendicectomy, but rather the relief of intraperitoneal tension. If there is scope for this the general principle for the urgency of surgery is unaltered, and I do not think that the watching and waiting policy is likely to be revived in the case of general peritonitis, except in those cases where the condition of the patient does not appear to warrant any operation. Anything short of appendicectomy here appears to be rarely successful, and if the patient will not stand this by all means give Nature a chance to localize the infection.

In conclusion I would suggest that the treatment of acute appendicitis should now be standardized on the following lines irrespective of the length of the illness:

- For acute appendicitis limited to the appendix, appendicectomy without drainage.
- For appendicitis with general peritonitis, appendicectomy with cleansing of the peritoneum and perhaps temporary drainage.
- For appendicitis with local peritonitis, relief of tension with subsequent appendicectomy.

The last suggestion is not intended to imply immediate operation in all cases, and treatment by physiological rest and the application of heat may be as successful in the treatment of acute inflammation in the right iliac fossa as in other parts of the body.

Treatment which is based on success gradually becomes standardized by the profession and recognized by the public. Experiment gradually gives place to routine, and it is our business to see that our practices are based on sound principles. Immutability is not to be expected in human affairs, but pathological laws do not change greatly, and to lower the mortality of a disease we must either prevent it, or fashion our cure to meet the disease when its victim will best respond to the treatment.

## An Address ON

## APPENDICITIS.

DELIVERED AT THE NORTH-EAST LONDON POST-GRADUATE  
COLLEGE ON FEBRUARY 16TH, 1925,  
BY

JAMES SHERREN, C.B.E., F.R.C.S.,  
SURGEON TO THE LONDON HOSPITAL.

DURING the year 1923, according to the Registrar-General's statistics, there were 2,826 deaths (1,608 male and 1,218 female) registered as due to appendicitis in England and Wales. There has been a little fluctuation in the death rate from year to year, but this was the largest number of deaths yet recorded; in 1913 it was 2,529 (1,387 male, 1,142 female). These figures cannot be considered exact, as cases of resulting intestinal obstruction, peritonitis, or other direct complications are not necessarily included, but they do give us an approximate idea. When we consider that the majority of cases of acute appendicitis occur in the young it is a serious figure, and in itself would be sufficient excuse for venturing to take up your time by speaking to you on a subject about which you might think there was nothing more to be said.

The damage done, however, is by no means limited to this loss of life. Among those that recover, in many there

has been an enormous waste of working time and much suffering that could have been prevented if the condition was surgically treated while it was still appendicitis. In the hospital to which I am attached we still get these cases too late—for example, in the twelve months preceding September 30th last 102 cases of acute appendicitis (57 male and 45 female) were admitted to my firm's beds at the London Hospital; of these only 27 were within the first twenty-four hours of the attack—the most favourable time for operation—and these were almost the only cases which could be treated as uncomplicated appendicitis. We should have advanced far from the day when it was stated, "The disease is essentially a variety of peritonitis; its manifestations, its effects, and its possibilities are those only of peritonitis. Whatever be the antecedent condition, an attack of appendicitis is not in evidence, and, indeed, does not exist until the peritoneum is implicated." We should now say that the disease has ceased to be simply appendicitis when this has happened, and that cure is no longer certain by simple removal of the appendix.

I wish specially to direct attention to the symptoms, particularly, but not entirely, in so-called chronic appendicitis. I say advisedly, as I have repeatedly said before, pain starting in and confined to the right iliac fossa is not the symptom of appendicitis. This conception of the symptoms dates, I feel sure, from the time when much of our knowledge was based on swellings in the right iliac fossa; the disease was called perityphilitis, of which inflammation of the appendix was not the only cause. No surgeon saw the case while it was still appendicitis; he was not called in until pus was diagnosed and the pain had become right-sided. That is, however, ancient history, and yet the number of individuals with right-sided pain who are admitted to hospital as acute or chronic appendicitis, or are seen after the appendix has been removed, without relief, shows no diminution. It is for these reasons—delay in submitting cases to operation and want of appreciation of the exact symptoms—that I consider there is still need for education in the matter of diagnosis and treatment.

Sometimes the delay in operating on acute cases is on the part of the public, who think, excusably, that as the appendix is on the right side, pain produced by its inflammation must be right-sided also. But in the majority of cases the patient has seen a medical man, and here there should now be no excuse for delay in recognizing the condition because the pain is general, on the other hand, cases of right-sided pain are still sent into my beds at hospital by medical officers of that institution as appendicitis.

There is now no sufficient reason for considering the symptoms of appendicitis to consist of pain in the right iliac fossa. Even the early writers on acute cases is on this country correctly realized its symptoms and mentioned the general nature of the pain, although they did not lay sufficient stress on it or always act on that knowledge. Treves spoke of it, but in his last contribution this was not insisted upon, and in his last contribution these words occur: "Removal of the appendix is also to be recommended in chronic appendicitis, in those examples in which there are no active attacks but in which there is abiding discomfort in the right iliac fossa with exacerbations of uneasiness." These, of course, are the cases in which appendicectomy is unlikely to bring relief. Tubby, in his excellent little monograph, published twenty-five years ago, was one of the first to direct sufficient attention to it, and writes: "A sudden and severe pain in the abdomen is in nearly every case the first symptom. Its situation is, during the first twenty-four to thirty-six hours, all over the abdomen." Lockwood also drew attention to it. Battle and Corner are perfectly clear on this matter. In a paper read at the Medical Society in 1907 by Sir Holburt Waring on "Some surgical affections of the right iliac fossa which simulate appendicitis," he wisely prefaced his illustrative cases with this observation: "I shall also restrict my remarks to those cases in which the cardinal clinical symptoms of an attack of acute or subacute appendicitis have been manifested—by these I understand abdominal pain commencing usually in the umbilical or epigastric region." In the most widely read student's textbook of surgery (Rose and Carless) the symptoms are correctly given, as they are in

the admirable article on the subject in the new edition of Choyce's *System of Surgery*.

Early in my dealing with this disease I recognized that pain confined to the right iliac fossa was not a symptom of appendicitis, acute or chronic. The first case that brought this home to me was in 1905, when I operated on a girl of 18 with pain in the right iliac fossa of three days' duration, in whom careful examination of chest and urine had failed to elicit any abnormality. Operation revealed a normal appendix, and the pain recurred as before. It was not long before I was convinced of the failure of appendicectomy to cure cases of right-sided pain in so-called chronic appendicitis; the results demonstrated the incorrectness of the diagnosis. I have taught for at least fifteen years that right-sided pain is not evidence of appendicitis, and I have published these remarks in several papers. It seems obvious from what I have quoted that the teaching in the hospitals of London must be on correct lines, as I have mentioned teachers at most of them. In spite of this, however, it seems difficult to get the correct symptoms realized; the idea is still fixed among many that appendicitis is the cause of right-sided pain. It may be the mental effect of the situation of the appendix, allowing the pain to fit its anatomical position, but it is most likely due to want of sufficient accuracy in teaching and writing, and also lack of differentiation between pain and tenderness.

In acute appendicitis the pain in the first instance is generalized, it is diffuse, usually umbilical or epigastric, and only later, when there is peritonitis or local peritoneal irritation, is the pain in the right iliac fossa. In a first attack of acute appendicitis the pain never starts in the right side. Appendicitis should be the last, not the first, disease to think of in a patient with pain starting in the right side of the abdomen. It is conceivable that if the appendix is buried in adhesions as the result of a previous acute attack the pain may commence locally. In a considerable experience of this condition I have known this to happen twice only. When we come to consider the cause of the symptoms, the overdistension of the appendix or irritation of its wall, it is obvious why the pain is generalized. The nerve supply is from the abdominal sympathetic, and it is not until there is irritation of parietal peritoneum or structures beneath it that the pain is local. The march of the symptoms is always the same—pain first; it never starts with vomiting, diarrhoea, or a rise of temperature. We are all familiar with attacks of pain in the right side of the abdomen accompanied by vomiting, sometimes by a slight rise of temperature, and more common in women. These are never appendicular in origin, but all need careful investigation, and at present in many of them the most we can say is that they are associated with ptosis. There are, however, more serious causes of acute right-sided abdominal pain, which may necessitate immediate or remote surgical treatment. I would mention leakage from a chronic duodenal ulcer, carcinoma of the pelvic colon, or any part distal to the caecum, tubal diseases, twisted ovarian tumours, renal conditions, and last, but not least, thoracic diseases. The last we should always bear in mind, as it still causes difficulties in diagnosis, and cases of pneumonia are yet often admitted into the surgical beds of a hospital. In some cases an attack of right-sided pain is due to a lymphadenitis of the group of glands in the ileo-caecal region, usually tuberculous in nature. The following is an excellent example:

A nurse was sent into the sick-room with a provisional diagnosis of appendicitis. She had been seized with pain in the right side of the abdomen six days before; it doubled her up and made her vomit. Her temperature was 99°, her pulse 100. The pain was entirely right-sided. Her temperature and her pulse rate remained the same, but her pain increased in severity and there was marked tenderness and slight rigidity in the right iliac fossa. Eleven months previously I had operated on her for tuberculous glands region. As her condition was getting worse I operated on March 7th, 1924, three days after admission, and found a mass of cascading glands extending upwards from the ileo-caecal angle. I evacuated the mass and closed the abdomen; the pain was at once relieved; she went out a month later, and remains well. The appendix was normal to naked eye and microscopic

Right-sided renal conditions should never be mistaken for appendicitis; the pain is never general, and the sym-

ptoms of the two are entirely different, yet such mistakes are by no means infrequently made. I will give a typical example:

A girl of 18 was sent to see me by her medical man because she had had no relief from appendicectomy. I obtained the following history: for years she had had attacks of pain in the right side, which she described as very bad, and which often made her vomit. Six weeks previously the appendix had been removed during an acute attack, and shortly after leaving hospital she had had further symptoms. On abdominal examination I discovered a definite renal tumour, which proved at operation to be a hydronephrosis.

An attack of right renal colic due to a calculus in the ureter is by no means infrequently diagnosed as acute appendicitis. It has been reported by R. F. O'Neill<sup>1</sup> that 25 per cent. of the patients in the Massachusetts General Hospital who had operations for ureteral calculi had had a previous operation for appendicitis or some other supposed intra-abdominal lesion without relief.

What, then, are the symptoms of acute appendicitis? There is the onset, usually sudden, of general abdominal pain, often waking the patient from sleep in the early hours of the morning. There may be no rise of pulse rate, and a high temperature is uncommon; it may be normal, but within twelve hours is usually from 99° to 100°. There is at first superficial tenderness, and deep tenderness is present in the right iliac fossa, beneath the liver, or per rectum, according to the position of the appendix, but the initial pain, as felt by the patient, is the same and the superficial tenderness remains the same. The symptoms are perfectly clear—general pain, local tenderness. We can probably all recall cases of this nature in which it was supposed that the patient had eaten something that disagreed or had "ptomaine poisoning," the disease not diagnosed until a swelling in the right iliac fossa made its appearance, or in the former cases matters were precipitated by an aperient. It is a common idea among patients to attribute all pains to some external influence, such as food taken, or to some half-forgotten injury, rather than to definite abdominal disease.

Symptoms such as I have described call for immediate operation. No aperient should be given, nothing but water by the mouth and morphine, if necessary, after the diagnosis has been made. Early removal when the inflammation is confined to the appendix would not only abolish the death rate from appendicitis, but would restore the patient to health and work in a very short time—eight or nine days in bed, and work resumed in four weeks.

Look at the other side of the picture: the patient is seen on the third day with obvious peritonitis; whatever treatment is then adopted—and I shall discuss this later—if recovery takes place it will be after a long illness, resulting in the loss, perhaps, of months of work or education. Or, again, the patient comes under observation on the sixth or seventh day with a localized mass; if operation is performed at once or delayed, much time is lost, and even if the patient returns to work within two months it is usually with a weakened abdominal wall, the result of drainage. There are also the risks of infection of other abdominal organs, the chest, and also intestinal obstruction.

In all that I have to say about the management of the later cases of acute appendicitis I want this to be borne in mind—there is only one treatment, and that is appendicectomy; the question to be discussed is at what time it is safest and best to operate. There is no exception to the rule that in acute appendicitis the appendix should always be removed while the disease is still confined to it; this is usually within the first twenty-four hours; occasionally we may be able to do it later. But if the patient has been seen medically there is no need for even this delay; most could be removed within the first twelve hours, and the earlier the better. Drainage is then unnecessary, and work is resumed within a very short time. When the patient is seen later, either with diffuse peritonitis or with a localized swelling, I am of the opinion, as I have been for many years, that the death rate is less, the disability time shorter, the complications fewer, and the abdominal wall stronger if operation is delayed. In the first paper that I published on the treatment of acute appendicitis, in 1905,<sup>2</sup> I wrote of these patients that they should be tided over the attack if

possible and the appendix removed later. This has been the rule in my wards at the London Hospital, and nearly twenty years' experience has only served to strengthen the opinion that this is the best treatment. Love<sup>9</sup> has written two papers on this subject based on a review of over 2,000 cases at the London Hospital under the care of all the surgeons. He found that the mortality in 221 cases operated on within twenty-four hours was 0.9 per cent. Excluding these, of cases which were treated by immediate operation at all stages after the first twenty-four hours the mortality was 5.8 per cent.; of those treated on delayed lines 3.5 per cent. He stated also that complications are three times as common in those late cases operated on immediately. I consider that these two papers are sufficient justification for the line of treatment I have advocated and adopted at the London Hospital since I first began to operate. The only change I have made has been to greater conservatism and more patience in dealing with cases of appendix abscess.

My routine is as follows: If there is reason to suppose the disease is still confined to the appendix, immediate operation; if it is not, the patient is put in the Fowler position, as much water allowed by mouth as is needed, unless there is vomiting, when continuous saline is given by the rectum and the stomach washed out; no aperient or enema is allowed. Morphine is administered subcutaneously if necessary, and a four-hour chart of pulse and temperature is kept. As a rule, within twenty-four hours the condition improves and the temperature begins to fall. I do not allow anything beyond water till the pulse and temperature have settled for twenty-four hours; an enema is given at about the same time. Too early feeding sends the temperature up at once. I have often kept the patient for six or seven days on water in this way. I have been astonished at the way in which large swellings gradually disappear under this treatment. If there is no improvement, the simplest operation is done—drainage; no attempt is made to search for the appendix; it is removed if it presents itself. When an abscess needs opening it should be through a small incision where it is pointing; if it can be felt per rectum it should be left until there is obvious fluctuation and opened by this route and a tube inserted. This can usually be removed in forty-eight hours. When abscesses have been drained or when swellings have taken considerable time to disappear, the patient is sent out and returns in three months for appendicectomy. It is astonishing how few adhesions are present and how usual it is for the appendix to show no sign of perforation, even when, from the escape of a concretion, one knows it has perforated.

The more experience I have of this method, and the more thoroughly it is carried out, the more I am pleased with it. I am convinced it shortens convalescence; the death rate is much less and there is an absence of complications such as intestinal obstruction, residual abscesses, and ventral herniae. But it requires skilful nursing and confidence on the part of the patient and friends. There must be no weakening on the subject of "food to keep up the patient's strength."

Before leaving the subject of acute appendicitis I should like to say a word on the increase of the disease and also on the change in sex incidence. The increase in the number of cases was remarkable between the years 1895 and 1905; this has been shown from the Bristol records by Rendle Short,<sup>10</sup> as well as by myself. The increase has been little since then, although the disease is certainly not on the decline. There has, however, been a remarkable change in the sex incidence. In 1903 I found, in the London Hospital cases, it was 2.5 times as common in the male sex; in the same year Grey Turner<sup>11</sup> found it about the same. In 1907 among 311 cases at the London Hospital there were 65 per cent. males; in 1922, among 625 cases, there were only 55 per cent. males. In my own acute cases at hospital in a year before September 30th, the percentage was about the same. This change in sex incidence has also been noted by Rendle Short.

Let us now pass to chronic appendicitis. In spite of all that has been said such a condition does exist, but it is not characterized by pain in the "appendix" region. I hold very strongly that a patient with pain confined to

the right iliac fossa with tenderness is not suffering from chronic appendicitis, and removal of the appendix is unjustifiable. It is because of its failure to relieve pain here that many have become sceptical of its existence. In America, where operations for "chronic appendicitis" were much more common even than in this country, many writers have drawn attention to the failure of appendicectomy to cure. A recent paper had as its title "Chronic appendicitis—is it a myth?"<sup>12</sup> and a dictum of a physician is quoted which runs: "There are two kinds of appendicitis—acute appendicitis and appendicitis for revenue only." Connell,<sup>13</sup> in a paper on pseudo-appendicitis, records failure to cure in 48 out of 212 patients operated on by himself, and draws attention to the fact that "After eliminating all demonstrable pathologic conditions that might possibly be confused with 'chronic appendicitis,' there remains, in certain cases, some cause for pain in the right iliac fossa, other than the appendix, the exact cause of which is as yet not definitely known."

Stanton,<sup>14</sup> in 1911, wrote as follows: "In our cured cases of chronic appendicitis the pain has been almost constantly referred to as epigastric or mid-abdominal rather than right inguinal. On the other hand, nearly all the patients not benefited by operation complained of right inguinal pain as one of their chief symptoms. . . . Our uncured patients almost without exception complained of pain in the right lower quadrant as their chief symptom." Chalfant<sup>15</sup> stated that "the results of operation for chronic appendicitis are among the poorest in surgery."

In the discussion on the subsequent course and later history of appendicitis after operation, at the Medico-Chirurgical Society in 1905, Treves,<sup>16</sup> who opened it, gave details of cases of failure to relieve. After eliminating such causes as incomplete removal of the appendix and persistent sinus, there were seven cases of persistent pain in the right iliac fossa, two of mobile kidney, and one renal calculus, all obviously cases operated on for right-sided pain.

In 1913 I wrote as follows:<sup>17</sup> "I first wish to direct your attention to pain in appendicitis—in the initial stage of the acute attack; it is generalized, and later shifts to the right iliac fossa. In chronic appendicitis I have been in the habit of teaching that pain is not in the right iliac fossa, and, if here, its principal seat is elsewhere. Less would be heard of failure to relieve symptoms by the removal of the appendix if we were sceptical of the sole appendicular origin of pain which is limited to the right iliac fossa."

When cases of pain in the right iliac fossa are excluded, there remain two definite groups in which chronic abdominal symptoms are certainly due to disease of the appendix. It may show itself first by attacks of pain in the abdomen, generalized or in the epigastric or umbilical region, severe but of short duration; and secondly, by dyspeptic symptoms, sometimes accompanied by haematemesis and occasionally by colicky pains and irregularity of the bowels. Removal of the appendix, as I have known it advised, to cure headaches or pains in the joints seems to me unjustifiable unless we have definite evidence from abdominal symptoms that the appendix is diseased.

I am beginning to doubt if it is ever justifiable to operate for what is supposed to be chronic appendicitis through a small incision. Certainly in cases in the second group, in which dyspepsia is diagnosed as being due to appendicular disease, it is never so—the whole abdomen must be explored. I have had to operate on numerous patients with gastric ulcer, duodenal ulcer, and gall-bladder disease in whom the appendix had previously been removed through a small incision in the right iliac fossa on the diagnosis of appendix dyspepsia. I will give examples of both types of disease.

I operated recently on a patient with the following history: A man, aged 32, was transferred to my care at the London Hospital by Dr. Robert Hutchison. He had not been in good digestive health for nine months following a severe attack of epigastric pain which lasted about an hour. Since then he had suffered from flatulence, and had had seven or eight attacks of upper abdominal pain, each lasting about seven hours. He was a stout man with no tenderness in the abdomen. A test meal showed lowered acidity. I explored the whole abdomen on January 23rd, 1925. The gall bladder on external examination

was normal, and there were no enlarged glands. I opened it; the mucous membrane was normal, and bacteriological examination of the bile showed it to be sterile. The stomach and duodenum were normal. The appendix was enlarged to the size of my index finger, and was adherent at its base. On cutting into it its walls were thickened; it was strictured at its base and contained muco-pus.

This is typical of the first group, and the diagnosis can only be made certainly if there is definite tenderness in the right iliac fossa during an attack. To show how necessary general exploration may be I will give you another example.

In 1919 I was asked to see a lady with a view to removing her appendix for dyspepsia. The following was the history given me: a year previously she had waked in the middle of the night with abdominal pain, diagnosed as acute appendicitis. She was kept in bed fourteen days. Since then she had had much nausea and occasional abdominal discomfort, both waking her and keeping her awake, and three months previously a milder attack of nocturnal pain. The report after a barium meal was that she had visceroptosis. Acting on the rule I have laid down, that although you may diagnose appendix dyspepsia you should never act on it—that is, never be content with removing the appendix alone—I found an atrophied adherent appendix, which I removed. On exploring the upper abdomen the cause for her abdominal pain became evident—there was cholecystitis with gall stones.

In chronic appendicitis causing dyspepsia the pain is not right-sided, although during an attack there may be tenderness in the right iliac fossa, and pressure here causes epigastric discomfort. But I wish to press home the fact that in these cases thorough examination of the whole abdomen is necessary at operation; only then can a certain diagnosis of appendix dyspepsia be made.

The object of choosing this subject has been to draw attention to the necessity of early operation in cases of acute appendicitis and to the care necessary in their diagnosis; and secondly, to warn you against too readily diagnosing chronic appendicitis—it is a disease that does exist and cause symptoms, but is not nearly as common as is often supposed.

## AN ANOXAEMIC TYPE OF INFANTILE ATROPHY.

C. A. BOTWOOD,  
M.B., Ch.B.,

BY

H. S. RAPER, C.B.E.,  
M.B., Ch.B., D.Sc.,

AND

EDITH WILLOCK, M.B., B.Ch., B.A.O., D.P.H.

(From the Department of Physiology, the Victoria University of Manchester, and the Manchester Babies' Hospital.)

THE term "atrophy" is used to describe a condition in infants which is characterized by an obstinate refusal to gain weight and thrive, in spite of dietetic or medicinal treatment, and in whom no cause can be found to account for this failure to grow. Atrophy is seldom associated with dyspepsia. If this is present at all it is very slight, quite insufficient to account for the infant's lack of progress, and quite possibly a result, rather than a cause, of the condition. In a few cases, however, there may be a history of previous dyspepsia, following which the atrophic state becomes evident; such cases may be classified as dyspeptic atrophies and may or may not respond to dietetic treatment. Again, atrophy may be due to endocrine or vitamin deficiency, and this type responds to the appropriate treatment. There is still, however, a form of atrophy which fails to respond to dietetic, endocrine, or vitamin treatment, and it is with cases of this kind that this preliminary note is concerned.

It is a common experience that at necropsies on cases of infantile atrophy little or no organic change is revealed which throws any light on the causation of the disease. This in itself might suggest that some physiological factor, other

than those mentioned above, is at fault. The idea that these particular cases are due to the disorder of some fundamental physiological function led to the consideration of the possibility of anoxaemia, either general, due to some deficiency in the functioning of the lungs, or local, due possibly to capillary stasis in the intestine as a result of initial digestive disturbances of either a mild or severe type. Regarding the former, it is well known that failure to saturate the blood in the lungs with oxygen, or deficient saturation brought about by other means, can profoundly affect the physiological condition of an animal. The subject has been fully dealt with by Haldane<sup>1</sup> and need not be elaborated here. That cyanosis and anoxaemia may occur in premature infants has been recorded by Bakwin,<sup>2</sup> who has described the results of treatment of two such cases with oxygen. About the occurrence of local want of oxygen in a tissue or organ, however, we have few or no data. It is true that this must play a part in certain well recognized pathological states—for example, in the liver and kidney in cases of mitral stenosis and in other conditions of circulatory failure, either local or general. Whether simple capillary stasis can occur in a single organ due to localized abnormal conditions and thus be a cause of local anoxaemia is, however, not so certain. It may be remembered that surgical shock is generally believed to be associated with widespread capillary stasis. The phenomena of shock can also be closely simulated in animals under anaesthesia by injection of histamine, which is a product capable of production by tissue breakdown. It does not appear inconceivable therefore that, under certain conditions, dysfunction of a tissue may be brought about locally through the action of toxic substances produced by bacterial action and that this may have, as a concomitant, local anoxaemia due to failure of the capillary circulation.

These were the underlying ideas that prompted us to try the effect of oxygen administration in certain cases of infantile atrophy. The cases are not as a rule cyanosed, but a slight degree of this condition may sometimes be observed. It seemed that a direct answer to the question whether a generalized anoxaemia was present would be best obtained by determining the results of oxygen therapy. On the other hand, oxygen therapy in localized anoxaemia due to capillary stasis would only act by increasing the dissolved oxygen of the blood, and this might be expected to yield good results only if continued for a considerable length of time and if the local anoxaemia were not severe.

The results we have obtained have so far been promising, and although the work is by no means completed it seems worth while placing them on record at this stage of the inquiry, which promises to be a long one. The preliminary experiments were carried out by two of us at the Leeds General Infirmary, through the kindness of Dr. C. W. Vining, but the greater part of the work has been done at the Manchester Babies' Hospital. For the facilities accorded to us there we are very greatly indebted to Dr. Catherine Chisholm. The cases chosen for oxygen treatment have been those which, after a period of dietetic treatment, have shown themselves to be refractory, as judged by failure to gain weight. In these cases digestive disturbances are never a marked feature, although they may occur, and are then of a mild type. When failure to gain in weight was established and the child was still on a diet to which it had not responded, the oxygen treatment was commenced. Thereafter the composition of the diet was not changed, but increased amounts of food were given as necessitated by the increase in weight and appetite of the child. The oxygen treatment was carried out in the small closed cot which was exhibited by us to the Physiological Society two years ago.

It consists essentially of an air-tight box (29 in. by 18 in. by 20 in.) with a glass lid and apertures for admitting oxygen at a known rate and for sampling the air within it. The infant is placed inside on a hammock. A small fan inside serves for mixing the contained air and providing for its movement. No arrangements are made for removing the carbon dioxide which accumulates while the infant is in the cot. In a two-hour period the carbon dioxide content of the air rises to between 2 and 3 per cent., depending on the size of the child and the amount of movement it makes. The oxygen is admitted from a cylinder provided with reducing valve and pressure gauge, and passes through a modified Pitot's tube, whereby, after a preliminary standardization, the rate of flow can be determined. After placing the child in the cot, the

glass lid is clamped on, the fan started, and oxygen rapidly admitted in sufficient amount to produce an atmosphere in the cot containing about 45 per cent. of oxygen. When this is attained (in four to six minutes) the flow is diminished to that amount which is necessary to maintain the oxygen concentration at about the same level. The infant is kept in the cot for two to two and a half hours and then removed for feeding, etc. It is then replaced in the cot, the air again enriched with oxygen, and so on for a further period of two to two and a half hours.

This treatment has been carried out during the day only. At the commencement the period of treatment with oxygen is limited to two hours on the first day, four on the second, and is increased to a maximum of about eight hours by the fourth day. The length of time during which it has been carried out has varied between two and three weeks. Except for one case which died within two days, and in which treatment was only instituted when the child was almost moribund and had lost weight rapidly, most of the infants treated have responded with a notable gain in weight, which has been continued after the treatment was stopped. Since the treatment has been continued over a period of two or three weeks it was necessary to rule out the factor of coincidence, because atrophic infants may occasionally begin to gain weight for no apparent reason. We have now treated 16 cases, of which 13 have shown a satisfactory gain in weight within a week from the beginning of the oxygen administration, and in our opinion this cannot be accounted for as a mere coincidence, but is due to the treatment.

It is possible that the mere increase of carbon dioxide in the air in the cot might be responsible for the good results obtained. A number of cases have therefore been treated in a similar cot in which the oxygen content was kept at the usual atmospheric level, but the carbon dioxide was allowed to accumulate. Of 5 cases thus treated, 4 began to gain weight slightly, whereas 1 remained stationary. The gain in weight was not so marked as that obtained in other cases treated in the oxygen-enriched air. All these 5 cases subsequently gained weight, but at a much more rapid rate when treatment with oxygen-enriched air was instituted. The following brief data with weight charts illustrate the kind of result obtained in successful cases.

## CASE I.

A male infant was admitted to hospital at the age of 2 months with a history of loss of weight and some dyspepsia: he was pale and thin but not wasted, and nothing abnormal was detected on examination. During nine weeks in hospital the infant's weight remained obstinately stationary in spite of various changes in diet; throughout this period his appetite was poor, but dyspeptic symptoms were slight; vitamin and glandular extracts produced no beneficial results.

CASE I.—Weight Chart. Feeds: Week 1—simple milk and water; week 2—Bengerized milk and water; weeks 3 to 6—lactified milk and water; weeks 6 to 15—Bengerized milk and water; week 16—simple milk and water. A, admission; D, discharge.

Ultimately the infant was placed in the oxygen cot for three weeks, the diet remaining the same in type as during the three previous weeks. While in the cot he gained 1 lb. in weight and another pound was added during the ensuing three weeks before discharge. The child's appetite commenced to improve after the institution of the cot treatment; the colour also improved and the muscular tone became much more firm.

## CASE II.

A male infant, aged 2 months, was admitted with a history of failure to gain weight and of some previous mild dyspepsia; the type of food had been altered two or three times without pro-

ducing any good results. On admission the infant was pale, with flabby muscles, but on the whole development was quite good. No abnormalities in the organs were present. The weight after six weeks was the same as on admission, though the appetite had been fair and no dyspeptic symptoms had been present. During

CASE II.—Weight Chart. Feeds: Week 1 to discharge—simple milk and water. A, admission; D, discharge.

twenty-three days in the oxygen cot, on the same form of diet, 12 oz. of weight were gained, and a further 17 oz. in the interval between the termination of the cot treatment and discharge. Muscular tone and general condition had also improved markedly since the commencement of the oxygen treatment.

## CASE III.

A male infant, aged 1 month, was admitted with an indefinite history of failure to thrive in spite of partial breast-feeding. He was, on admission, a small, pale, and slightly wasted infant, with a spotty skin; the Wassermann reaction was negative. The child was tried on various kinds of food, and for a time even received some breast-milk feeds; he took feeds well, with only one slight initial attack of dyspepsia, but he completely failed to put on weight, and after six weeks in hospital only weighed 1 oz. more than on admission. With no alteration of diet, the infant was then placed for three weeks in the carbon dioxide cot (in which the carbon

CASE III.—Weight Chart. Feeds: Week 1—simple milk and water; weeks 2 to 4—Bengerized milk and water; weeks 4 to 15—lactified milk and water; week 17—simple milk and water. A, admission; D, discharge.

dioxide was allowed to accumulate but the oxygen content was kept approximately equal to that of the atmosphere). During this period 7 oz. of weight were gained. After three days' interval he was transferred to the oxygen cot for three weeks, and in this cot 17 oz. were gained, and another 27 oz. before discharge six weeks later. Later on the child developed some septic areas on his scalp with subsequent glandular enlargement, and also some auricular discharge. All these conditions, however, cleared up satisfactorily, and on discharge the infant's general condition had greatly improved.

Since the small increase in carbon dioxide in the air of the cot without any oxygen enrichment was beneficial, we are inclined to accept this as supporting the view that some degree of general anoxaemia was present in these cases and that this was the cause of their failure to thrive. The increased ventilation of the lungs which the greater amount of carbon dioxide produces would in any case be of benefit if anoxaemia were present, but one would expect a better result by enriching the air with oxygen as well. This has been our experience.

It is obvious that further data from a much larger series of cases will have to be collected before more can be said about the treatment than that placed on record here. The work is therefore being continued and extended.

We wish to express our thanks to the Medical Research Council for defraying a part of the expense of this work.

## A METHOD OF TREATING INFECTED ULCERS.

BY

S. A. PFANNENSTILL, M.D.,

LATE CHIEF PHYSICIAN OF THE MUNICIPAL HOSPITAL, MALMÖ, SWEDEN.

In 1910 I published an account of a new method for the treatment of infected ulcers, based on principles which had not been previously applied to therapeutics. The ordinary antiseptic treatment of ulcers does not always yield satisfactory results, owing to the fact that even the strongest antiseptics, applied to an ulcer, only kill the surface bacteria, without reaching those at even a slight depth, these being destroyed eventually by the general bactericidal powers of the patient. This destruction is, in general, satisfactory, except in the case of tuberculous, syphilitic, and certain tropical ulcers; but the time taken is often very long, which is very trying to the patient and the physician. I therefore set out to find a means of attacking the bacteria with a sufficiently strong antiseptic, not only on the surface of an ulcer, but also in the subjacent tissues. I thought this might be effected by the use of two substances which would interact to form a third substance with antiseptic properties. Moreover, since elements in the nascent state have enhanced chemical affinities, and consequently greater bactericidal properties, I wished to make use of this fact in the new treatment.

For the first of these substances I have used sodium iodide, administered orally, one of the elements in which is the highly potent iodine. This salt is non-poisonous, and in medicinal doses is ordinarily without unpleasant results; it is very quickly absorbed into the blood and is so carried by the circulation to the ulcer. There it meets some second substance, applied locally, which can set free iodine from the compound salt. Such substances are not difficult to find, the chemical combination of iodine with sodium being loose. It is not only freed by chlorino and the hypochlorites (Dakin's and Carrel's solutions) but also by any strongly oxidizing substance such as ozone and hydrogen peroxide. I have tried all these substances, and I generally prefer the peroxide solution as being the handiest and always constant in composition.

Iodine, for long considered one of our very best antiseptics, acts under these conditions in the nascent state, thus increasing its already great bactericidal properties. I must also draw attention to a subordinate point that may in some cases be important. Hydrogen peroxide, when in acid solution, frees iodine more easily and to a greater extent than in a neutral solution, the sodium radicle entering into combination with the acid. I therefore now acidify the peroxide solution with a small quantity of an acid, it does not matter which; I generally use acetic acid, but employ boric acid in treatment in the mouth, thus avoiding injury to the teeth.

*Practical Application of the Method.*

In the case of an ulcer on the surface of the body or the limbs I give sodium iodide in an average dose of 15 grains two or three times a day. Larger doses may be given, 60 to 90 grains a day, the effect of the treatment then being greater; but this entails some risk of iodism. Immediately after the first dose of sodium iodide the local peroxide treatment begins. The ulcer is covered by a layer of cotton-wool, not too thick, which is kept continually soaked with the peroxide solution dropping from a dropping-phial every tenth or fifteenth minute, or even more frequently. The more thoroughly the wool is soaked with peroxide the greater is the effect obtained. The strength of the peroxide solution must be kept at 1 to 3 per cent., generally 1 to 1½ per cent., because stronger solutions often irritate the sound skin around the ulcer. An addition of 1/4 to 1/2 per cent. acetic acid will prove quite sufficient for acidifying.

Since the blood contains most sodium iodide about one to two hours after its administration, special attention should be devoted during that time to the thorough soaking of the ulcer with peroxide solution. After the last dose of sodium iodide has been given for the day the local

treatment of the ulcer should be continued for at least three to four hours in order to make full use of the iodine which is still circulating in the blood and will be gradually excreted by the kidneys.

When the ulcer has invaded the deeper tissue layers, forming pockets, it is necessary to tampon the pockets loosely with gauze in order to bring the infected walls of the ulcer into intimate contact with the peroxide solution dripped on the gauze. Infected cavities in bones and joints are to be treated in the same manner. Fistulae, however, usually cannot be directly treated, it being difficult, or even impossible, to conduct the peroxide solution in sufficient quantity through the narrow ducts. It cannot be repeated too often or too strongly emphasized that the efficiency of the method depends upon there being an intimate and prolonged contact between fresh hydrogen peroxide and the infected surface to which sodium iodide is being carried through the blood vessels. A surgical operation will sometimes make a fistula suitable for this treatment.

For treating ulcerations in the nose the nasal cavity must be loosely plugged with gauze upon which the peroxide solution must be dripped as before indicated, care being taken that the patient's head is held back so as to enable the liquid to flow up into the nose. In treatment of affections in the mouth and throat the method of applying the peroxide solution must be changed. In the case of the mouth it is usually sufficient to rinse it frequently with peroxide at intervals of a quarter of an hour or less. For treating the throat a spray apparatus is necessary; different types are on the market, some being driven by compressed air. When hydrogen peroxide is being used for treatment of affections in the mouth and throat it must be remembered that it is not permissible to make the solution acid with the common acids, lest the teeth should be injured. The only acid suitable is boric acid, this being inoffensive to the teeth and quite effective in a 1 per cent. dilution.

The efficiency of this method of treatment is due to the antiseptic agent, iodine, being generated in the nascent state locally; it operates at a deeper level in the infected tissues than do other antiseptics, the iodine being generated not only on the surface but also at some depth under it. Nevertheless, we must presume that even this strong bactericide cannot itself kill all the microbes in an infected ulcer; to do this it must be aided by the bactericidal powers of the patient. These are always a very important factor in the healing of every local or general infectious disease. The method suggested is designed to help the body to conquer a local lesion, thus shortening the duration of the infection and accelerating its cure. In cases where the body cannot unaided overcome a local infection this procedure will supply an additional bactericidal auxiliary.

*Conditions in which the Method has proved Successful.*

The ulcerations in which the method has been employed may conveniently be divided into two groups—namely, common infected ulcers and tuberculous ulcers. In the former group may be included all ulcers appearing spontaneously, or after trauma, or infected by pyogenic organisms; in the latter all tuberculous and lupoid ulcerations. All ulcers belonging to the first group are generally treated successfully by the method, but since its application is less convenient than the usual methods of treatment it should be reserved for serious cases, in which these latter methods are less efficacious, such as phagedenic chancre and infection in open joints and bones. The method has proved very valuable in treating infectious conditions and ulcerations in the mouth and pharynx, such as mercury stomatitis, pyorrhoea, gingivitis, and angina necrotica (Vincenti). It has an extensive application in dental surgery for treating pyorrhoea, but the gum must first be separated from the teeth to enable the peroxide solution to reach the actual infected spot.

The method has been frequently employed in treating tuberculous and lupoid ulcerations in the nose and throat, but with variable results. This is due partly to the histological structure of the tuberculous ulcer and partly to the mode of action of the method. Tuberculous tissue commonly extends deeply below the free surface of the

ulcer, superficial tuberculous infections being comparatively rare, and the extent of the remedial action is necessarily limited. It follows that only in the case of superficial tuberculous ulcers can a thorough and permanent cure be expected; with deeper infections no lasting cure is to be obtained. Superficial healing will often occur, but deeper down the tubercles continue to grow; sooner or later they will sprout through the cicatrix or beside it.

Laryngeal tuberculosis deserves special mention. I have treated a large number of cases by my method, and in many of them I have obtained a perfect and lasting cure; others, which remained unaffected, indicating the correctness of the two principles mentioned previously. Careful attention must be paid to the condition of the lungs. If these are too extensively diseased it is no use trying to cure a local tuberculous affection. Advanced and progressive lung tuberculosis, with its corollaries of anaemia and cachexia, forbids the application of the method, since the patients can barely tolerate it, and the body has lost its power of recuperation. The treatment of local tuberculosis may be summed up as follows. For tuberculous and lupoid ulcers a complete and lasting cure can be obtained if the infection has not penetrated too far into the tissues, but if the infection is deep, as is commonly the case, only a superficial healing, or none at all, is to be expected.

#### The Treatment of Tropical Ulcers.

It is well known that external ulcers are very numerous and difficult to cure in the tropics. Not only are there those ulcers which commonly occur in temperate climates and which, owing to unfavourable tropical conditions, progress unfavourably, but also there are ulcers which are indigenous. I believe that my method should be particularly useful in the treatment of these tropical ulcers, and, since the British Empire includes the most extensive tropical dominion in the world, I have ventured to submit my proposal to the BRITISH MEDICAL JOURNAL in the hope that it will thus reach those regions where it is likely to prove of most use.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### TRACHEOTOMY TUBE WORN FOR OVER SIXTY YEARS.

I saw recently, in consultation with Dr. Benson Goulding, a case that may be worth recording.

It was that of an old lady, aged 81, who when 10 years old got "scarlatina followed by croup," and was tracheotomized very urgently in her home by Mr. Hutton, of "railroad catheter" fame in this city. She still wears the tube. She quotes Mr. Hutton as saying that she was only the third case of tracheotomy in Dublin, the other two having been performed in the Richmond Hospital.

The operation was a high tracheotomy. The voice when she stops the tube is quite good and pleasing. The larynx appears normal in phonation, but the rima glottidis does not open from ankylosis of the arytenoids. She has been perfectly healthy since the operation except for some rheumatic

arthritis, has never had bronchitis, and is mentally as active as the average individual of 40.

A noteworthy feature of her case is that she can never leave the tube out without putting in a substitute at once, for fear of choking, the fistula, in spite of its age, still preserving its tendency to close.

In her 20's she spent two winters in Canada, crossing Lake Ontario in the mail sleigh on her way home. She married at about 28 and has had seven children, five of whom are alive.

Dublin.

ROBERT WOODS.

#### DIPHTHERIA IN OLD AGE.

DIPHTHERIA is essentially a disease of childhood, but cases may be met with in any age period, and, though relatively infrequent in old age, it is by no means as uncommon as the paucity of recorded cases would suggest. Former hospital statistics understate the incidence, because, as one might expect, the tendency is for practitioners to treat aged patients in their own homes. In 1913 fourteen notifications relating to cases of diphtheria in patients of over 60 years of age were received in the metropolitan area, but only two of these cases were admitted to hospital. In the previous year nine such cases were notified, but none of them received hospital treatment. The following table is self-explanatory:

Cases of Diphtheria in the Fever Hospitals of the Metropolitan Asylums Board, 1895 to 1914.

Total number of cases (all age groups), 110,741.

		Males.	Females.	Total.
Aged 60 and upwards	...	15	21	36
Deaths	...	3	7	10

In early life diphtheria is slightly commoner and more fatal in the female sex. In old age both the incidence and mortality rate are much higher in females. With one exception all the cases I have been able to trace from the literature have referred to female patients. The following is an instance of diphtheria in a patient of advanced age.

A woman, aged 94, was admitted to the Grove Hospital in July, 1924. On admission an exudate covered both tonsils and there was slight bilateral cervical adenitis. The clinical diagnosis was confirmed bacteriologically, and she received 21,000 units of antitoxin. Five days after admission the throat was clean, and the subsequent course was uneventful. She had no paralytic sequelae, and except for a slight albuminuria there were no complications. She was discharged well after a stay of thirty-eight days in hospital.

In some of the recorded cases the exudate consisted of a small patch on a somewhat atrophic faucial mucous membrane. The false membrane showed little tendency to spread, and deliquescence was sluggish. Paralysis, noted in some of the cases, did not differ from the type observed in younger patients. The mortality must have been unfavourably influenced by the age of the patients and the consequent increased liability to intercurrent affections.

Laryngeal forms are very rare in old age, but their occasional occurrence has led Akesson to emphasize the importance of examining for the diphtheria bacillus in the laryngitis of elderly people. As J. D. Rolleston has pointed out, the prognosis in the laryngeal diphtheria of adults is grave on account of the likelihood of an extension of membrane to the bronchi and lungs. The laryngitis from which George Washington died, at the age of 67, was supposed by Bretonneau to have been diphtherial.

From the notes of a case recently reported by Muir it would appear that there is a possibility that some of the cases of rhinitis in the aged may have a diphtherial origin. The non-specific therapeutic value of horse serum is well recognized, and it is interesting to note that in the cases recorded by Birt and Keyes the administration of antitoxin was followed by the apparent cure of gout in one case and of a varicose ulcer in the other.

## A CASE OF CHOREA IN INFANCY.

THE absence from Dr. Mary Bertram's series (*BRITISH MEDICAL JOURNAL*, March 14th, p. 496) of any case of chorea under the age of 3 prompts me to record one seen by me some years ago, frequently mentioned to students, but not hitherto given more permanent record. The patient was a female infant, aged 1 year and 10 months. The choreic movements were of recent origin and moderate severity, and there was quite definite carditis with mitral systolic bruit conducted outwards. The child had also a very rachitic head which had been wrongly considered to be hydrocephalus, beaded ribs, and other evidences of rickets. Furthermore, there was a very neurotic family history, the father being a confirmed epileptic. The subsequent history of the case is unknown to me. The patient was also seen in consultation by my senior colleague on the staff of the Children's Infirmary, Dr. Peter Davidson, whose opinion coincided with mine that the case was undoubtedly one of rheumatic chorea.

HUBERT ARMSTRONG, M.D.

## SPONTANEOUS RUPTURE OF THE HEART.

THE report of the following case had been written out before the publication of the paper on a similar case by Drs. Skeen and Rutherford Dow in the *BRITISH MEDICAL JOURNAL* of February 7th (p. 262). The cases have certain features in common. In neither was the heart enlarged, the accident did not take place during violent exertion, and in both there was marked arterio-sclerosis of the coronary vessels. In the case now reported the spontaneous rupture can also be attributed to "a diminished blood supply with consequent secondary degenerative changes in the heart muscles."

A man, aged 70, recently attended at Dr. Kahan's surgery and complained that during the previous night he had been seized with severe pain in the epigastric region. At the time of examination the pain was practically gone, and nothing abnormal was detected. Five days later he again called and stated that he was feeling much better. Three days afterwards he appeared at the surgery about 10.30 a.m. At 10.45 another patient offered to allow him to go into the consulting room before his turn, as he looked so bad. He, however, did not move. Dr. Kahan and I immediately examined him. We could not feel his pulse; the corneal reflex was practically absent; the breathing was slow and stertorous; and the cardiac sounds were not audible. In about ten minutes from the onset of the attack the respiration ceased and the man was dead.

*Post-mortem Examination.*—The body was well nourished, with a tendency to obesity. As a cerebral haemorrhage was suspected, the brain was examined first, but no sign of a haemorrhage was found; the membranes were thickened and somewhat adherent to the surface of the brain; the cerebral arteries were definitely thickened. On opening the chest the pericardium was seen to be well covered with fat. The pericardial sac, opened *in situ*, contained about 8 oz. of blood. The heart appeared of normal size. The valves were competent, but showed evidence of sclerosis. The cardiac musculature was flabby and apparently in a state of degeneration. Near the apex, and adjacent to the septum, on the internal surface of the anterior wall of the left ventricle, was a tear  $3/4$  in. long. On attempting to pass a probe through this rent it came through only at the lower end to the external surface of the heart. The muscle immediately surrounding the rupture was necrotic. The coronary arteries were sclerosed and their lumen narrowed. On the inner surface of the aorta there were numerous atheromatous plaques. The lungs were slightly emphysematous. The liver was enlarged and congested, and the gall bladder contained ten small gall stones. The spleen was congested. The kidneys were of average size, but their cortex was narrowed and contained two or three small cysts. Their capsules were somewhat adherent, and their surface showed only slight granulations. The stomach contained some semisolid pulsatious food. The other organs showed nothing abnormal.

The sudden attack of pain of which the man first complained may have been due to gall-stone colic, or may perhaps have been associated with the splitting of the endocardium and myocardium, and death resulted when the epicardium gave way.

Spontaneous rupture of the heart usually occurs during violent exertion; but this was not the case here, as the man was sitting quietly when the catastrophe happened.

The heart was not enlarged. It may perhaps be deduced from this that the tension in the arterial system was not greatly increased. Monro<sup>1</sup> writes:

<sup>1</sup> *Manual of Medicine*, fourth edition, pp. 353-354.

"There is reason to believe that certain toxic agents, such as alcohol and lead, give rise to degenerative changes in the arteries through their direct influence, and without necessarily causing increase of tension. It is possible, too, that endogenous poisons resulting from perverted metabolism may have a similar effect."

Of course, the sclerosis of the coronaries, by interfering with the nutrition of the heart, would tend to its atrophy. This man was a compositor, but had done no work for several years. He was not a teetotaler. Though there was extensive cardio-vascular degeneration, the man apparently enjoyed good health till about one week before his death.

London, E.L. M. COHEN, M.B., Ch.B.Glas.

## TRAUMATIC INTUSSUSCEPTION.

JUDGING from the scantiness of the literature on the subject it is clear that the condition described in the following case must be rare.

A girl, aged 10 years, fell across a chair at school and hurt her abdomen. She fainted, but rapidly recovered, and returned home complaining of pain in the umbilical region. She vomited many times during the night and next morning. When seen twenty-two hours after the accident the temperature was subnormal; the pulse was about 100, very irregular, and rather thin. The tongue was dry and she was still vomiting (pure bile). The abdomen moved fairly well, but was tender all over the left side and slightly rigid, especially in the upper left segment. As it was feared that rupture of the intestine had occurred, immediate laparotomy was performed. A little free blood was found in the peritoneal cavity, and considerable extravasation was present in the layers of the great omentum and in the lesser sac, though not sufficient to form a swelling. Tracing up the ileum from the caecum an intussusception was found at the lower end of the jejunum, the upper portion entering the lower for about one and a half inches. A few feet higher up another "double intussusception" was found, both upper and lower segments entering the gut for about one inch and meeting in the middle of the tumour. In both lesions the gut was absolutely normal in appearance, calibre, and texture, and obviously no obstruction, either circulatory or intestinal, had arisen. Both lesions were undone with the greatest ease, leaving no trace of where they had occurred.

Obviously they were due to violent and irregular peristalsis following the trauma. Recovery was only slightly delayed by influenza.

## LONG SURVIVAL WITH CANCER OF THE BREAST.

ALTHOUGH it has long been known that patients suffering from carcinoma of the breast may live for a long time, the following case may prove to be of interest.

Mrs. M. B., aged 78, first consulted me on January 1st, 1924. She complained of headaches and a feeling of weakness, but had no pain. Practically the whole of the left side of the chest was eaten away. There were no respiratory movements and no physical signs of acting lung on that side. The heart appeared normal. The walls of this cavity were insensible to touch or heat or cold, but bled readily when touched. There were no evidences of metastases.

I obtained the following history: Twenty-five years ago she noticed a lump in the left breast which slowly grew until at the end of a year it was about the size of a golf ball. She was then operated upon by a surgeon who is now dead (I could not discover the scope of the operation). Twelve months after the operation there was recurrence in the scars, which she refused to have operated upon. The growth gradually ate into the chest, ultimately producing the condition I have described above.

She died on March 2nd, 1925, conscious to the last, but extremely weak. There was at no time evidence of metastases. A *post-mortem* examination was refused.

Preston.

J. BERNSTEIN, M.B., M.R.C.S.

# THE GOLD TREATMENT OF TUBERCULOSIS.

## PRELIMINARY REPORT BY THE MEDICAL RESEARCH COUNCIL.

VARIOUS gold compounds have from time to time been used in the treatment of tuberculosis. Recently a soluble complex salt of gold and sodium—namely, sodium aurithiosulphate, which has long been known to chemists, and is now made available under the trade mark of "sanocrysin"—has been introduced to therapeutics as a treatment for tuberculosis by Professor Moellgaard of Copenhagen, who has found that it has the advantage of dissociation into complex ions, so that toxicity due to free gold ions is avoided. Such toxic effects as this compound produces in tuberculous but not in normal subjects are attributed to destruction of the bacilli and increased liberation of tubercle toxins; and Professor Moellgaard has also prepared an antitoxic serum for use, when necessary, to counteract these ill effects. The results of experiments on animals and of numerous trials on human patients in some Danish hospitals have been fully described in his book on the *Chemotherapy of Tuberculosis* (autumn, 1924). Critical summaries of these results and of other work in Denmark have been published recently in the *British Medical Journal*<sup>1</sup> and in the *Lancet*. Clinical trials are now proceeding also in Germany and in Canada.

Professor Moellgaard very courteously gave to the Medical Research Council a full supply both of the gold salt and of the protective serum for clinical trial in England, but desired that the preparations should not be made available for general use in medicine until the results of these trials were completed. In December he and his chief colleague, Dr. Secker, visited England, and made a personal communication on the subject to those who were asked to try the preparations; while Dr. Secker remained in London long enough to visit several hospitals, advise on the selection of cases, and give the observers invaluable help during the treatment of individual patients by instruction drawn from his own wide experience.

The preparations were issued by the Council, as on the similar occasion of the introduction of insulin to therapeutics, only to those who were not engaged in private practice—that is, to whole-time professors of medicine or to tuberculosis officers. The Ministry of Health was kept in close touch with the work through a liaison officer. On account of the general interest aroused by discussion of this method of treatment, the Council thinks it desirable to issue this preliminary report on the early results of cases so far treated in Great Britain, and to explain its further policy.

Work in England has been in progress for less than three months; it has not been on a large scale, but the value of the opinions formed has been enhanced by the arrangement which used several observers of small groups working at first independently of each other rather than one observer of a large group. It was evident, when the observers subsequently met in the first conference upon which this report is based, that there was so great a divergence of opinion upon the value of the drug that any single observer, relying solely on his own experience, might easily have been led to a summary opinion that would have been unduly emphatic in his judgement for or against the

treatment. The report deals solely with clinical results, and does not consider the laboratory evidence for the effect of the gold salt on tubercle bacilli or infected tissues, nor that for the protective action of the specific serum.<sup>2</sup>

Each dose of sanocrysin was dissolved in 10 c.cm. of distilled water and injected intravenously. The usual amount was 0.5 g. for the first injection and then repeated injections of 1 g. each at intervals of about three days, unless a severe reaction on the part of the patient occurred and compelled delay until the reaction had subsided. The total amount used in any case was generally about 5 or 6 g., and the injections were rarely continued until the goal suggested by the Danish experiences was attained—namely, a final state in which the last injection produced no rise of temperature.

The specific serum, usually from horses immunized by diaphyte tubercle vaccine, though at first a weaker calf serum also received trial, was injected into the muscles in doses of 20 c.cm. Its action is supposed to be that of neutralizing the flood of tuberculous toxins liberated by the action of the gold salt on the infected tissues, and thus of lessening the general severity of the reaction to the chemotherapeutic injection. In cases with heavy tuberculous infection the serum was used either before or together with the first gold injection as a preliminary measure. In mild cases it was not used until a reaction of some severity had occurred, and in many instances it was never used at all.

### EFFECTS OF THE INJECTION OF SANOCRYSIN.

Vomiting was often noticed as an immediate effect within a few minutes of the injection. In one control patient, without evidence of tuberculous disease, there was nausea and prolonged anorexia after three injections, but no rise of temperature or any other reaction. There were no other control observations of cases with fever from known causes other than tuberculosis, so that the evidence is not sufficient to ascertain whether the gold salt can be used as a test to distinguish non-tuberculous from tuberculous febrile states. In a group of five cases of pulmonary tuberculosis that were clinically mild but radiologically moderately extensive, there were slight pyrexia and trifling albuminuria, but no other features of reaction. The gold salt in amounts up to 5 or 6 g. therefore seemed to be non-toxic for patients with only slight tuberculous lesions.

Severe reactions were generally produced in cases of more extensive infection. The temperature rose within a few hours to 103° or 104°; but there was no case of hyperpyrexia or of critical fall. Vomiting often recurred, but diarrhoea was not often observed. The patient felt ill, depressed, and lost appetite. A metallic taste was sometimes complained of, and there was a tendency to ulceration of the mouth and throat. The rise of temperature lasted three or four days, but was generally less with each successive dose. After the second or third dose rashes often appeared, like those of measles or scarlet fever, and not often itching. In one case an erythematous rash persisted for a fortnight and was accompanied by an outbreak of many indolent open sores. The rashes were seen in cases where no serum had been given. They were perhaps more frequent in cases of closed tuberculous infection.

Albuminuria was a common occurrence, and in some cases exceeded 1 per cent., though it did not last long. No oedema resulted and there was no evidence of persistent renal lesions. Measurements of blood urea were not made in any of the cases of severe albuminuria. In one necropsy, where there had never been more than trifling albuminuria, 8 per cent. of the total metallic gold injected was found in the kidneys on death twenty-eight days after the last injection.

<sup>2</sup> These matters are discussed by Professor Moellgaard in the paper published in this JOURNAL on April 4th.—Editor, BRITISH MEDICAL JOURNAL.

<sup>1</sup> It may be added that a paper by Professor Moellgaard on "The theoretical basis of the sanocrysin treatment of tuberculosis" was published in the BRITISH MEDICAL JOURNAL of April 4th (p. 643). In it he fully explained the theoretical considerations which led him to employ sodium aurithiosulphate, related some of the experiments on animals he has carried out, and indicated the precautions which should be taken in the administration of the drug.—Editor, BRITISH MEDICAL JOURNAL.

of sanocrysin. Gold was proved to be excreted by the bowels and by the kidneys after an injection of sanocrysin. Jaundice of a grave nature, which in the Danish experience was a very rare event, occurred in another patient who died, and a relatively large amount of gold was found on analysis of the liver.

Features strongly suggesting that the gold salt had a direct action at the site of the tuberculous infection were often seen. Thus, in the lungs a focal reaction was evidenced by local pain, a sense of tightness, and by prolonged tachypnoea. This was in at least three instances aggravated by the development of a very critical state in which the pulse became rapid and feeble and the patient so collapsed, though the temperature did not fall seriously, that great anxiety was aroused as to the chances of recovery. Except for a local increase of crepitant râles, there were no clear changes in the physical signs in the lungs during these focal reactions. Cough, however, was generally increased and sputum was at first more abundant if the patient had strength for expectoration. Subsequently both cough and sputum tended to lessen.

Headache was never intense. A general state of depression and lack of vitality, together with loss of weight, tended to develop in cases of extensive infection after a course of treatment, and this retarded subsequent recovery in the hospital wards.

#### EFFECTS OF THE INJECTION OF THE PROTECTIVE SERUM.

Clinical experience varied on this point. At some hospitals nearly every patient had severe serum sickness, perhaps with its own rash and vomiting, and certainly with severe joint and muscle pains. Other observers never saw such effects. The differences were not explained by reference to any particular batch of serum, or to different effect of calf or of horse serum respectively. There were, however, no examples of dangerous anaphylactic phenomena.

It was difficult to form a clear conclusion as to the benefit of the serum. Some observers thought they had proof of its power to control albuminuria and focal reactions in the lungs, if given early and before these features became serious; others were not convinced. In general, serum was freely used for severe cases of infection. A few trials were made of the influence of the serum on the general state of a tuberculous patient apart from the use of sanocrysin, but they led to no demonstrable results.

#### SUMMARY OF CLINICAL RESULTS.

Clinical experience in Britain has confirmed the description in Professor Moellgaard's book of the immediate effects of sanocrysin as seen in Danish hospitals. The drug does appear clinically to have a specific action on tissues infected by tubercle bacilli, and the severity of the constitutional reactions does appear to be directly related to the intensity of the tuberculous infection. Further, the drug seems to have but slight toxicity for human patients who are not infected by tuberculosis, though in this respect very few control observations have been made. On account of the severity of the reactions in the first tuberculous patients chosen for treatment, no observer at the beginning felt justified in deliberately making control observations in other febrile infections. For the same reason no one cared to begin straight away with the treatment on a large number of tuberculous cases, but each observer preferred to select three or four individual patients and proceed cautiously.

The total number of cases covered by this preliminary report is small—about thirty, of whom twenty-two definitely had tuberculous infections of the lungs. Two of the pulmonary cases died, death in one hopeless case being perhaps accelerated by the treatment, and occurring in the other unexpectedly as the result of toxic jaundice. The remaining twenty do not lend themselves to any numerical analysis. Uncomplicated pulmonary tuberculosis is a disease of which few physicians can confidently foretell the progress, upward or downward, during any given period of two or three months, which was all the time available for these preliminary observations. But it was the opinion of those observers who had had most experience in dealing with

consumption that the early cases of open tuberculous infection of the lungs did show some evident improvement, though there was no dramatic benefit, such as that seen with insulin or salvarsan in their corresponding diseases. On the other hand, cases with more advanced disease did not stand the treatment well, and the condition of some of these has been made worse. The latter experience accords with that of Dr. Seeker of Copenhagen. Serious cases of long standing cannot endure the treatment in its present form.

There were two cases, not included in the preceding twenty, in which most striking improvement followed at once upon the use of the drug, both the patients having lain three months in hospital previously without making any advance. One appeared to be a case of closed tuberculosis of the lung, spreading out from hilum glands, though it could not be proved that the pulmonary inflammation was caused by tubercle bacilli and not by some other smouldering infection. The other was a case of tuberculous peritonitis with an encysted collection of fluid that vanished at once upon treatment. In each instance the patient showed the rash and rise of temperature that in other proved cases of tuberculosis have followed the injection of sanocrysin. No case of pleural effusion was treated in this preliminary group because the results in this condition would not have offered any decisive evidence. Lupus of the skin, spinal caries, renal tuberculosis, and tuberculous glands are now being treated, but their progress is not sufficiently advanced to be included in this report.

The evidence, therefore, despite the relatively poor results in open pulmonary tuberculosis—and that is unhappily the commonest form of tuberculosis—is sufficiently encouraging to demand further clinical study. This is particularly so in view of the one experience common to all observers—namely, that the drug seems to exert a specific action on tuberculous tissues. The Medical Research Council expects that many months will pass after the issue of this preliminary report before any further definite conclusions can be drawn. Trial on a larger scale is now justified, and it is hoped to widen the field of work with the help of more observers. But the Council is of opinion that such further trial and extended observations are imperatively required before it can be clearly stated that this gold salt is of value in the treatment of tuberculosis and before it should be made available for general use in medical practice in Great Britain.

#### SUMMARY OF CLINICAL OBSERVATIONS.

The following section briefly summarizes the clinical observations at the several places where the treatment was used. In every patient radiograms of the chest were taken before, during, and after treatment.

##### ST. BARTHOLOMEW'S HOSPITAL (PROFESSOR F. R. FRASER).

One case, aged 30. General pulmonary tuberculosis; tubercle bacilli found once. Total gold salt used, 5.25 g. Severe reaction at first, but final injection of 1 g. caused no rise of temperature. No definite change.

##### LONDON HOSPITAL (PROFESSOR A. W. M. ELLIS).

Five cases of pulmonary tuberculosis, one case of tuberculous meningitis, and one non-tuberculous control. The general impression of the results was definitely unfavourable.

—, aged 17. Four years' history. Extensive pulmonary tuberculosis both lungs. General condition good; had gained 1 st. in weight. Tubercle bacilli found once during treatment. Total gold salt used, 6.5 g. in eight weeks. Severe reactions, fever, rash, ophthalmic reactions, albuminuria, loss of weight. Gradual recovery on stopping treatment to conditions very much as on admission. No change in physical signs. Result: No change.

—, aged 53. Three months' history of pleural effusion and fibrosis. General condition fair. Tubercle bacilli present on one occasion only. Total gold salt used, 2.75 g. Gold salt discontinued because of prostration, albuminuria, prolonged nausea, and anorexia. Severe serum sickness. Lost weight and has not regained it two months after cessation of treatment. Result: No improvement; apparently made worse by treatment.

—, aged 23. Two years' history. Extensive pulmonary tuberculosis both lungs. General condition good; had recently gained 1 st. in weight. Tubercle bacilli disappeared from the sputum during treatment but reappeared later in large numbers. Total gold salt used, 1.5 g. Gold salt discontinued because of vomiting

and continuous hiccup. Prolonged anorexia. Fever, rash, and albuminuria. Three weeks after last injection, onset of hectic temperature with physical signs indicating rapid and extensive spread in the area of pulmonary involvement. No subsequent improvement. Is going steadily downhill. Result: Treatment led to extensive spread of the disease and marked general deterioration.

—, aged 36. Three years' history. Extensive chronic tuberculosis both lungs. General condition excellent; afebrile. Albuminuria. Renal function normal. Tubercle bacilli absent. Total gold salt used, 5.5 g. Moderately severe febrile reactions, nausea, and vomiting. Ten days after the last injection temperature became hectic and has remained so, with marked increase in physical signs and evidence of rapid spread of the infection. At the same time there appeared a very severe exfoliative dermatitis, apparently identical with that seen in severe arsenical poisoning. Result: Extensive spread of the disease; severe exfoliative dermatitis.

—, aged 19. Three years' history. Extensive chronic pulmonary tuberculosis of left lung; early involvement of right. General condition excellent; afebrile. Tubercle bacilli disappeared during early part of treatment, but reappeared later in increasing numbers. Total gold salt used, 7.5 g. Treatment followed by severe and prolonged reactions with fever, rash, albuminuria, and breathlessness. Severe serum sickness. After the third injection the temperature never again reached normal, the physical signs in the chest increased both in quantity and in extent, and tubercle bacilli reappeared in the sputum. Subsequent injections failed to influence the course of the disease. Serum, when given, resulted in violent reactions with rigors and collapse. The resulting situation was a very difficult one. It was obvious that the patient was going steadily downhill. It was decided to try and increase the concentration of the drug, even though, on account of the reactions, serum could not be given. Two injections of 1 g. were therefore given, with one day intervening. Four hours after the second injection there was dyspnoea, cyanosis, and blood-stained frothy sputum. Death occurred in two hours. There was no *post-mortem* examination. Result: Death.

—, aged 9 months. Tuberculous meningitis. Total gold salt used, 0.4 g. in two days. No evidence of any effect was seen. Death occurred on third day. Result: No influence detected.

In addition a case of lymphadenoma or Hodgkin's disease was treated as a control. The patient received three injections of the gold salt and no serum. There was no rise of temperature, no albuminuria, and no rash, but nausea and prolonged anorexia resulted.

#### ST. MARY'S HOSPITAL (PROFESSOR F. LANGMEAD).

Three cases of pulmonary tuberculosis. The early results were unfavourable and one patient died, apparently in consequence of the treatment.

—, aged 18. General condition good, but tubercle bacilli abundant. Total gold salt, 1.5 g. in four days, and over 200 c.cm. serum. Vomiting, diarrhoea, rash, fever, albuminuria, and definite serum reaction. Focal reaction in lungs. On tenth day after the last injection of gold salt, jaundice appeared and rapidly deepened. The patient died with haemorrhage from the bowels twenty-nine days after the last injection.

Necropsy found spreading tuberculosis in the lungs and recent tuberculous ulceration of the bowels. There was only one hypertrophied kidney, and that showed tubular nephritis. The kidney was not analysed for gold, but in the liver was found 0.028 g. of gold—that is, 4.75 per cent. of the total metal injected.

—, aged 32. Early disease of right apex, afebrile. Tubercle bacilli present. Total gold salt, 5 g. Fever, rash, loss of weight, albuminuria; general condition deteriorated, but is now improving, and temperature is again normal. Physical signs unchanged and tubercle bacilli still present in sputum.

—, aged 29. Peribronchial fibrosis and doubtful physical signs, but tubercle bacilli present; temperature normal. Total gold salt, 6 g. Fever, severe serum sickness, loss of weight, slight albuminuria, pain in chest, and increased expectoration. General condition at first worse, but later improving. No tubercle bacilli in sputum in last three weekly examinations, but patient developed pleurisy seven weeks after treatment was ended.

#### ST. THOMAS'S HOSPITAL (PROFESSOR H. MACLEAN).

Only early or slight pulmonary tuberculosis was treated, in five cases of which four had tubercle bacilli present. They were in fairly good general health, with few symptoms and generally very little pyrexia. Gold salt was given in doses of 1 g. at four to seven days' interval up to a total of 4 or 5 g. No serum was used. The reactions were slight, a little pyrexia, some albuminuria, and increase of cough. No focal pain in the chest, no anorexia. All the five cases have subsequently improved, but it is difficult to decide whether this improvement is more than would have been effected by ordinary hospital treatment. This group is, however, of great importance as a control to show that the gold salt exerts little obvious effect on the general health of patients with only mild tuberculous infections.

—, aged 27. Three months' history. No tubercle bacilli. Gold salt given, 4.5 g. No reactions except slight albuminuria persisting since fourth dose. General condition improved. X-ray examination

showed disappearance of triangular opacity in right axilla which had suggested tuberculous infiltration.

—, aged 21. Six months' history. Tubercle bacilli present. X-ray examination: Disease upper third of both lungs. Very dense right apex, moderately dense left. Some fibrotic contraction right apex. Had begun to improve already with hospital treatment. Gold salt given, 4.25 g. Slight temperature reactions. Transient albuminuria for five days after fourth dose. Result: Previous rate of improvement maintained or accelerated. Final radiogram shows no change except increased contraction right apex, though radiogram taken during reaction showed increase of shadows. Tubercle bacilli present on discharge, but some evidence of fragmentation.

—, aged 23. Three months' history. Tubercle bacilli present. X-ray changes of medium density both lungs, occupying one-third of pulmonary fields. Gold salt given, 5.25 g. No definite reactions. Irregular pyrexia persisted. Attack of pleurisy after four weeks. Result: General condition improved; x-ray examination, no change.

—, aged 18. Short history. Tubercle bacilli present. X-ray examination: Medium opacity upper half both lungs. General condition good. Gold salt given, 5.25 g. No marked reactions. Result: General condition improved. Sputum—no tubercle bacilli on March 9th, 1925. No sputum since.

—, aged 24. Eighteen months' history. Tubercle bacilli present. X-ray examination: Very slight changes left apex. General condition not very good. Two doses, each followed by slight pyrexia. Rash resembling erythema multiforme two days after second injection; increased slowly during next six days; began to fade on fifteenth day. Treatment in consequence delayed, and is now being completed.

#### UNIVERSITY COLLEGE HOSPITAL (PROFESSOR T. R. ELLIOTT).

Four cases, of which two appeared to be cured by the treatment, though the evidence was not conclusive. In two pulmonary cases with tubercle bacilli in the sputum the results were, on the other hand, definitely unfavourable.

—, aged 18. Bilateral apical infection with one year's history. Poor condition, though afebrile, and tubercle bacilli always in sputum. Total gold salt, 6.25 g. in thirty-four days, with 360 c.cm. serum. Much albuminuria, no rash, no severe serum sickness. Marked focal reaction in lungs, with pain, dyspnoea, and a serious circulatory collapse twice. Prolonged vomiting and anorexia. General condition worse and tubercle bacilli in sputum more abundant.

—, aged 29. A hopelessly rapid caseous tuberculosis, chiefly of right lung with less than six months' history. Tubercle bacilli in sputum. Patient so ill that he seemed unlikely to survive more than a couple of months. Total gold salt, 4 g. in eleven days, with 300 c.cm. serum. Slight albuminuria and no rash. Marked focal reaction in lungs with dyspnoea that persisted. Died four weeks after last gold injection, with repeated pulmonary oozings of blood.

Necropsy.—Necropsy confirmed the radiograms in showing that the caseous changes had spread rapidly into the left lung since treatment began; and the detachment of one large mass of caseous lung tissue loose within a cavity on the right side suggested that some unusually active process of destruction had been taking place. There was no tuberculosis outside of the lungs.

Disappearance of Gold from the Tissues.—Analysis found that of the total metallic gold given (40 per cent. of 4 g. salt—that is, 1.60 g.) 0.128 g., or 8 per cent., was still present in the kidneys. The percentage of gold to the weight of the kidney was 0.037. The liver retained a total of 0.012 g.—that is, barely 1/70 of the percentage found in the kidney. The lungs contained only traces that could not be measured. This rapid disappearance of the gold from the tissues where its effect was desired suggests that the salt should not be given intensively in severe cases, as advised by the Danish physicians, but at longer-spaced intervals.

—, aged 20. Tuberculous peritonitis with large encysted collection of fluid in the lower abdomen. Pleurisy at 14, with present x-ray evidence of fibrosis on right side. No tubercle bacilli in sputum and abdomen not explored. Condition stationary during three months' rest in hospital previous to treatment. Total gold salt, 4.5 g. in seventeen days and 80 c.cm. serum. Febrile reaction, with rash and some pain in right chest and in abdomen. The tumour had vanished by the time the last dose was given. No recurrence a month later, but still some chronic inflammation found on rectal palpation of the uterine adnexa. Patient gaining weight. Apparently a most definite improvement as the immediate result of treatment.

—, aged 14. Query localized tuberculous bronchopneumonia. Admitted for large quiescent tuberculous glands in neck, which were excised and microscoped. After anaesthetic for this operation the patient developed consolidation of left lower lobe, which took four weeks to clear up. X-rays subsequently showed much enlargement of hilum glands and a shadow spreading outwards in the middle of the right lower lobe. The patient was under medical treatment in hospital for three months, during which time there were no tubercle bacilli in sputum, but there was continuous pyrexia and varying loss of weight. Boy seemed seriously ill when gold treatment was begun. Weight 5 st. 7 lb. Total gold, 1.25 g. in six days. Severe and prolonged rash, rise of temperature, and fall of weight to 5 st. 2 lb. No focal reaction in glands of neck. Then recovery,

with temperature thenceforward normal, and rise of weight by 2 or 3 lb. weekly to 6 st. 5 lb. on discharge from hospital. Still faint x-ray evidence of fibrosis in area of earlier opaqueness in right lung. The boy was cured with unusual rapidity of his lung inflammation, which was not actually proved to be tuberculous, though its appearance was clinically identical with that of ilium tuberculosis.

#### CARDIFF (PROFESSOR S. L. CUMMINS).

Three cases of early pulmonary tuberculosis, of which two showed definite improvement, and one, whose preliminary course of treatment has only just been completed, feels better, although he has not yet started to regain weight.

—, aged 21. Early disease involving two lobes, but only slight in density. Fair general condition. Tubercle bacilli present. Total gold salt, 4.5 g. in five weeks, and 92 c.cm. horse serum. Moderate reactions after first four doses. Sputum ceased. Tubercle bacilli vanished. Lost 2½ lb. during treatment. Has now regained this and added about 4 lb. to original weight.

—, aged 28. Definite pulmonary disease right apex, with cavitation. Tubercle bacilli present in great abundance. Total gold salt, 6.5 g. in seven weeks, and 95 c.cm. horse serum. Moderate reactions and transient albuminuria after gold salt. Severe reactions after serum. Sputum diminished and tubercle bacilli greatly reduced in number. Has lost 9 lb. during treatment. Is now feeling "as he used to before illness," but has not yet started to regain weight.

—, aged 15. Dullness and bronchial breathing upper third right lung. Tubercle bacilli present in fair numbers. Good general condition. Total gold salt, 3.25 g. in five weeks, and 36 c.cm. serum. Reaction and slight albuminuria after first dose. Intense serum sickness. Lost 3 lb. at first. Has now put on 4 lb. Is still under treatment. Appears much improved so far. No tubercle bacilli in sputum on last three examinations.

#### EDINBURGH (PROFESSOR SIR ROBERT PHILIP AND PROFESSOR D. MURRAY LYON).

Work at Edinburgh was not commenced until January, and while a much larger series of cases was tried than at any individual centre in London, few of these have yet reached the end of treatment. In general the results seem favourable. Serum was sparingly used, and in many cases not at all. In some tuberculous cases the Danish antituberculin serum was used alone without the gold salt, and it was not seen to have any constant influence on the temperature curve. All the patients selected were without exception afebrile at the beginning of the treatment. In the pulmonary cases tubercle bacilli were present at the commencement.

**Immediate Effects of the Drug.**—The first dose of 1/2 g. sanocrysin produced either very little reaction or a rise of about 2° F., the whole disturbance as a rule passing off in twenty-four to forty-eight hours. In two cases the temperature reaction to the first dose was prolonged for about ten days, a swinging temperature increasing for the first three or four days, reaching to about 103° F., and then gradually disappearing. No albuminuria or rash followed the first dose. The second dose of sanocrysin was usually followed by much larger temperature disturbance, lasting a little longer than that of the half-dose, but in most cases each subsequent dose gave rise to a smaller temperature response, until in some cases no rise occurred at all. A large number of the cases complained of loss of appetite, and in some the anorexia was very severe; vomiting has been frequent—in some cases within a few minutes after each dose, in other cases a few hours later; or, again, occurring only in the early morning each day.

**Albuminuria.**—A considerable quantity of albuminuria might appear after the second or third dose and remain present for several days, gradually decreasing in quantity, even without the use of serum. Renal cells and casts were present in some of the cases, but there have been no other signs of renal irritation or nephritis. A case of tuberculous kidney showed no increase in albuminuria under treatment, but after four doses treatment had to be suspended because of recurring vomiting.

**Rashes.**—Skin rashes have appeared in about three-quarters of the cases, irrespective of whether they have had serum or not. The rashes have varied considerably in character, from fleeting erythemas and urticarias to persistent dermatitis. In some cases the whole rash disappeared in a few hours, and in many it lasted for three or four days. The rashes were judged by an observer who had clinical familiarity with those caused by extensive tuberculin treatment to be very similar to the latter. In one pulmonary case a severe reaction has persisted for about three weeks, the whole skin being inflamed, the tissues about the face swollen, and there has been a universal desquamation. Apparently this subject had had some previous skin trouble.

**Results.**—In three pulmonary cases with abundant tubercle bacilli and definite x-ray changes there was some improvement. Sputum was lessened, but a severe rash occurred in two, and in one of these there was persistent vomiting and anorexia. In eight other cases, including lupus of the face, renal tuberculosis, and scrofulous glands of the neck, no alarming features of reaction have yet been observed.

## British Medical Association.

### CLINICAL AND SCIENTIFIC PROCEEDINGS.

#### OXFORD DIVISION.

The second meeting of the year was held at the Radcliffe Infirmary, Oxford, on March 25th. Dr. A. W. NEILL was in the chair, and about forty members were present.

#### SKIN DISEASES IN CHILDHOOD.

A paper on some common skin diseases in infants and children was read by Dr. A. M. H. GRAY, physician for diseases of the skin, University College Hospital, London, and the Hospital for Sick Children, Great Ormond Street. He said that the skin of infants was very delicate, but was usually well protected by the attentions of parents and nurses, consequently bacterial infection was not very common. Streptococcal and staphylococcal infections were, however, met with. Streptococcal infection took the form of a bullous eruption, starting from the site of inoculation and spreading eccentrically. The rate of spread varied mainly with the virulence of the organism. Bullous impetigo or pemphigus neonatorum could be distinguished from syphilitic pemphigus by the symmetry of the latter, its tendency to affect the palms and soles, the presence of other types of lesion, and the malnutrition of the patient. In treating streptococcal pemphigus care must be taken to avoid loss of body heat, and large wet dressings should be avoided. The most convenient dressing was lin. calamine to which 1 or 2 per cent. of ammoniated mercury had been added; strips of linen were soaked in this and pads of cotton-wool applied outside. Staphylococcal infection took the form of multiple boils, which were seen in weakly infants. Incision and drainage, keeping the patient warm, and care as to feeding, were the lines along which treatment should be directed.

Infants (Dr. Gray continued) were very prone to eczema of the face and scalp. Two varieties were generally recognized. The commonest form started on one or both cheeks as a red itchy patch, and friction caused the eruption to spread over the rest of the face; the eyelids and perinasal region often escaped, as they were protected by their position from friction. Later the scalp might become involved, and eczematous patches develop on the trunk and limbs. This type occurred chiefly in fat children under 1 year old, and was seen mainly in winter. It appeared to be generally associated with overfeeding. Treatment consisted in reducing the quantity of the feeds, whether breast or bottle, protection of the face from the air by a suitable mask and from friction by fixing down the hands, and by avoiding exposure to extremes of heat and cold. Coal-tar ointment applied on the mask was most generally useful; 3 per cent. crude coal tar in pasta zinci (B.P.C.) acted extremely well. The tar should not be applied if much sepsis was present; septic crusts could be first dealt with by 1 in 1,000 flavine-starch poultices. The other type of facial eczema usually began on the scalp and appeared to be independent of the nutrition of the child; it was thought to be primarily of seborrhoeic origin, but usually responded to the tar ointment. In some cases 1 or 2 per cent. sulphur and salicylic acid ointment was of value.

In children past the first year of life eczema was less often seen except in association with septic infection. Streptococcal infection was, however, very common. Varying forms were seen. The ordinary impetigo contagiosa started as a small thin-walled blister which rapidly ruptured, but the serum exuding from the base of the blister dried to form a crust. The lesions were usually isolated and the spread was eccentric. In some cases, however, bullae were produced and the spread might be more rapid. Lotions were the most suitable for this condition, 1 in 1,000 flavine applied on lint or linen and changed several times daily being advised. In other cases slowly spreading blisters, which flattened down and dried up in the centre, but continued to spread at the edge, were found—the so-called circinate impetigo. This was treated by

dimite white precipitate ointment. Streptococcal infection was liable to occur in the deeper folds of the face, behind the ears, in the angles of the mouth, nose, and eyelids. Here fissures tended to occur, and these were often troublesome to heal. The point was to prevent the cracks from being opened when changing the dressings; this was easy except at the angles of the mouth, and here in troublesome cases it might be necessary to fix the angle of the mouth by a small piece of zinc oxide strapping after applying the weak mercurial ointment. The pale, dry, circumscribed scaly patches, known as pityriasis alba, seen on the faces of children were usually, though not always, of streptococcal origin. They often responded to an ointment of ac. salicyl. gr. x, ung. hydr. ammon. dil. ad 5j. Severe impetigo of the ear and surrounding area due to middle-ear discharge often spread to the scalp and produced a severe form of septic dermatitis with much secondary staphylococcal folliculitis. Such cases were extremely troublesome to treat, and required all the resources of the dermatologist. Impetigo contagiosa often complicated infection by animal parasites. In these cases, where scratching was a marked feature, ulceration occurred in some of the lesions and ecthyma was produced. Ecchyma lesions were best treated by tying up with 3 per cent. ammoniated mercury in pasta zinci (B.P.C.) after the crusts had been removed; and the parasitic condition, of course, must first be treated.

A condition often seen among children was an itchiness of the flexures of the elbows and knees, sometimes affecting the flexures, and also the sides and front of the neck and the face. The cause of the itching was still undetermined. The skin lesions seen were the result of friction. These cases could often be cured in the early stages by tying the affected areas with the coal-tar paste; more resistant cases often responded to x-ray treatment. An endeavour should be made to get these young patients well, because if the condition drifted on to adult life it was extremely intractable.

#### LABORATORY DIAGNOSIS OF ENTERIC FEVERS.

A paper on the laboratory diagnosis of the enteric group of fevers was read by Dr. W. T. COLLIER, honorary assistant physician to the Radcliffe Infirmary. It was based upon the investigation of the 20 cases of enteric admitted to the infirmary during the five years 1920-24. Of these, 12 were due to *B. paratyphosus* B, 6 to *B. typhosus*, and 2 apparently to mixed infections. There were no deaths. Of the 6 cases of typhoid, 3 occurred in three members of the same family. A rough clinical classification showed that only 8 of the 20 cases could possibly be described as severe; 4 were regarded as moderate and 8 as mild. The mild cases had an average febrile period of seventeen days; they were all cases of paratyphoid B, except one case of *B. typhosus* infection in a baby aged 2. It was this frequency of the mild case of paratyphoid B which led Dr. Collier to bring forward the question of diagnosis, for most of the cases treated outside the hospital had also been mild cases of paratyphoid B, and he felt convinced that a good many cases must escape detection. With a severe infection the possibility of typhoid was usually obvious enough to suggest an examination of the blood; but in the mild case this possibility might not even be considered. The only two diseases in his experience with which confusion tended to occur had been influenza and acute appendicitis. One case in the present series was sent into the hospital as a case of appendicitis, and he knew of two cases outside in which appendicectomy was performed before the disease was recognized.

In the diagnosis of enteric (Dr. Collier continued) three laboratory methods merited consideration—the white cell count, the Widal or agglutination test, and direct culture of the organism.

**White Cell Count.**—In enteric this showed a leucopenia and not a leucocytosis. It was unfortunate that several of the diseases from which typhoid might have to be distinguished—for example, influenza, tuberculosis, subacute bacterial endocarditis—also showed a leucopenia; but where a septic infection was in question the white count might be of great value.

**The Widal Reaction.**—This was the most generally useful means of diagnosis they possessed; in all the twenty cases, except one, it was positive at the first examination and in most of them to a dilution of 1 in 250. All the cases were examined by Dreyer's macroscopic method: in inoculated individuals this method was essential. Since this was an immunity reaction, depending on the formation of agglutinins, the test did not usually become diagnostic until the seventh to the tenth day. It attained its maximum on the eighteenth to twentieth day, and then fell, at first rapidly and later more slowly, and might persist for many years after the infection. A single dose of vaccine, on the other hand, produced a maximum response in a much shorter period, for which reason even to ten days was chosen as the optimum interval between doses. The Widal reaction remained positive for a very variable period after inoculation, but probably for never less than two years. Moreover, there was very great variation in the individual's response to the three components of the vaccine. It was interesting to note that detoxicated vaccine did not apparently produce a positive Widal reaction. As to the significance of a positive Widal reaction, it might mean one of three things: (1) active infection, (2) past infection, and (3) past inoculation with the particular organism. While diagnosis in an inoculated individual was a comparatively simple matter, it must be based on two or three comparative tests performed at three- or four-day intervals—and this delay, of course, detracted to some extent from its usefulness. Diagnosis was based in the earlier stages on a rise, in the later on a fall in the titre of the reaction. The phenomenon of coagglutination (occasional non-specific stimulation of agglutinin formation) did not in actual practice usually cause difficulty. Thus, especially in the inoculated, infection with typhoid might cause some rise in the A and B agglutinins, and a non-specific infection such as pneumonia might slightly raise the agglutinin titre of all three. The limitations of the Widal test were: (1) it did not usually become positive until the seventh to tenth day, and in rare cases might remain negative throughout; (2) it might only be evidence of a past infection, so that unless the clinical condition was suggestive of typhoid the "agglutination curve" must be ascertained by a second test after an interval of three or four days; (3) in all inoculated cases the same procedure was necessary, and the blood usually had to be examined thrice.

**Culture of the Organism.**—Much the most trustworthy method was that of blood culture. The disease commenced with a bacteraemia, and in the first week blood culture was almost invariably positive; it was therefore a valuable complementary test to the Widal reaction. After the first week the chance of cultivating the organism from the blood gradually diminished. The organisms were also present in the stools at a fairly early period, but their isolation was apt to be difficult and tedious, and the method was not therefore very useful for diagnosis. In the urine the organism was only present in some cases, and usually in the later stages.

#### MISCELLANEOUS CASES.

Mr. E. C. BEYERS showed a patient in whom he had performed aseptic resection of the colon for carcinoma by Fraser's method, and described the technique of the operation.

Mr. HUGH WHITELOCKE showed two cases for diagnosis: (1) A boy, aged 15, with a painless cystic swelling the size of a hen's egg at the root of the right side of the neck of four weeks' duration. Since first seen some days previously the swelling had undergone a change, and in view of the supervening redness of the skin Mr. Whitelocke agreed with the suggestion that it was probably a breaking down tuberculous supraclavicular gland. (2) A man, aged 40, with a painless general enlargement of the liver, slight cyanosis of the face and hands, and transient oedema of the feet. The liver, which reached the umbilicus, was smooth and firm, and had been first noticed to be enlarged six weeks before by the patient's doctor (Dr. Bingham Marshall of Buckingham) during the routine examination for an attack of bronchitis. There was no enlargement of the spleen, and various laboratory tests were negative. In view of the uncertainty of the diagnosis exploratory laparotomy was to be carried out at a later date (the condition was then found to be one of portal cirrhosis).

Mr. STEVENS showed a man, aged 47, also with hepatic enlargement. The history dated from seven weeks before admission to hospital, when the patient noticed fullness and flatulence after meals, with a subsequent feeling of weakness and loss of weight. The case was regarded generally as one of malignant disease.

## Reports of Societies.

### MORTALITY OF APPENDICITIS.

A MEETING of the Section of Surgery of the Royal Society of Medicine was held on March 4th, with the President, Mr. H. J. PATERSON, in the chair. A discussion upon the mortality of appendicitis was opened by Mr. JOSEPH E. ADAMS (whose remarks appear in full at page 723 this week).

Mr. R. J. McNEILL LOVE, who continued the discussion, referred to the two schools of thought with regard to the treatment of certain types of appendicitis; one school operated upon all cases as soon as diagnosed, whereas the other school in certain selected cases gave the acute inflammatory reaction an opportunity to subside before operating. In two articles in the *British Journal of Surgery* he had analysed a number of statistics referring to a total of 2,018 cases of acute appendicitis, of which 110 died, giving a mortality of 5.45 per cent. These cases were divisible into two types: (1) immediate operation, 1,677 cases with 98 deaths, a mortality of 5.8 per cent.; (2) expectant treatment, 228 cases, of which 8 died, a mortality of 3.5 per cent. All surgeons were agreed that in the early stages when the appendix was not perforated operation should be performed at once. The mortality in his series for operation within forty-eight hours of the onset was 2.2 per cent. of 718 cases. When the cases where operation was performed between the third and fifth days were considered it was found that the mortality (of 612 cases) was no less than 10.2 per cent. During this period natural immunity had been exhausted and acquired immunity was not yet established, and operation accelerated the absorption of toxins where the patient was least able to deal with them. For such cases the risks of expectant treatment were considerably less. The risk of rupture into the peritoneal cavity of a localized abscess was reduced to a minimum by permitting only water at first and later fluids by the mouth, and withholding all aperients. Fomentations were applied and Fowler's position adopted, and, if necessary, a glycerin enema was given to relieve discomfort. In his series there was only one case where the calamity of intraperitoneal rupture of an abscess occurred, and that followed the sudden distension of the colon by a soap-and-water enema. Of 228 cases in which expectant treatment was adopted, 151 (nearly 70 per cent.) subsided and were subsequently submitted to appendicectomy, with a mortality of 1.9 per cent. In the remaining 77 cases expectant treatment had to be abandoned and operation was performed, either because the general symptoms became more marked or because a local abscess formed which increased in size. The mortality of these 77 cases was 5 or 6.5 per cent., only a fraction more than the mortality of cases submitted to immediate operation, so that a brief delay, even when the symptoms did not subside, did not appreciably increase the mortality. When expectant treatment had been successfully adopted there remained the question of the best time for operation. In his series, 151 cases had been operated upon one week after the temperature and pulse were normal, but this period was probably too short, as it was found necessary to drain 40 per cent. of the cases. Sir George Beatson recommended operation when the temperature, pulse, and blood count were normal, the latter indicating resolution of the inflammation or the presence of merely sterile pus. A third school advocated operation after a delay of three months from the time when infection had subsided. In addition to the definitely lower mortality of expectant treatment there were also the advantages that immediate post-operative complications such as intestinal obstruction, faecal fistula, etc., were diminished, late sequelae such as incisional hernia were less frequent, and the operation itself was much simplified. Expectant treatment imposed a greater tax on the nursing staff and necessitated continuous supervision by the surgeon, and for these reasons was only practicable in hospital practice.

Mr. C. A. R. NIXON considered that the problem of the treatment of cases first seen about the fourth day was an exceedingly difficult one. In such cases where there was a

mass to be felt in the abdomen he usually adopted the expectant plan, but felt the responsibility of doing so to be very heavy, since the mortality of a slowly leaking abscess was very high. As regards the time for appendicectomy in delayed cases, he preferred to wait for three weeks after the infection had subsided, since he had known patients to die of general peritonitis when the period was reduced to one week after the temperature and pulse were normal. A still longer delay, on the other hand, meant denser adhesions and a more difficult operation.

Mr. CECIL ROWNTREE said he always adopted the plan of immediate operation. In cases at about the fourth or fifth day when the appendix was difficult to find he did not persist in the search, but merely drained; he performed the operation of removal of the appendix about three months later, when the inflammatory mass had disappeared, leaving singularly little in the way of adhesions, so that the operation was a simple one. His impression was that the mortality of appendicitis was definitely less now than it was ten years ago, and he suggested that the Registrar-General's figures, which showed an increase in the mortality, were accounted for by the number of semi-skilled surgeons now operating and to their persistence in removing the appendix in cases where it would more safely be left.

Mr. A. E. ROCHE related two cases which showed the extreme difficulty of deciding which cases were suitable for expectant treatment. In one case, first seen on the ninth day with an abscess, operation was delayed until the thirteenth day, when the appendix, with an encysted abscess in the omentum, was removed without pus being seen. It was possible to close the abdomen completely, and the patient made an excellent recovery. In the other case, first seen on the fourth day, operation was delayed on account of some doubt as to the diagnosis. On the eleventh day, after the temperature and pulse had been normal for some days, there was a sudden drop in the temperature with a rise in the pulse, and the patient rapidly succumbed. *Post mortem* pus was found up to the diaphragm.

Mr. H. S. SOUTAR invariably operated within an hour of making the diagnosis, although he agreed that operation was often very difficult about the third to fifth day, and required the highest degree of surgical skill and judgement. He used a small incision in order to limit the field, and did not persist in attempting to remove the appendix when it was not easily found. On the other hand, he knew of cases where the expectant form of treatment was followed with complete success. One country practitioner boasted that he never called upon a surgeon for cases of appendicitis, as abscesses when they formed invariably burst into the rectum. At the age of 65 this practitioner himself had appendicitis and refused to be operated upon. In due course an abscess formed which burst into the rectum, and complete recovery ensued.

Mr. H. W. CARSON thought that the time factor was not the only one to be considered. The age of the patient was also important. For children he considered the safest plan was to operate at once. But in the case of adults there was a period, generally about the fourth day, when an ill timed operation had to be concluded by draining a bleeding granulating mass left by the surgeon, although no pus might have been seen. He thought that one week's delay after the temperature and pulse had fallen to normal, in the cases treated expectantly, was insufficient, as the same state of affairs might exist then. There was one position of the appendix which called for operation without delay at any stage—namely, the 5 o'clock position, in which the appendix was hanging over the brim of the pelvis; in this event the diagnosis was made by rectal examination, for abdominal signs might be completely absent. He considered that the important question of pre-operative treatment had not received due attention from teachers of surgery; the adoption of the Fowler position, for example, was just as necessary before operation as after, and yet it was rarely practised as a pre-operative measure.

The President considered that in addition to the 5 o'clock appendix the retrocaecal appendix should be removed at once. His usual practice was to operate at once, and he nearly always removed the appendix; he thought that he only abandoned the search for the appendix in about 2 per cent. of cases. He asked Mr. Adams how, short of opera-

tion, it was possible to tell when the inflammation had spread beyond the appendix.

Mr. McNEILL LOVE, in reply, agreed that a week was too short a period to allow after the temperature and pulse fell to normal, as was proved by the fact that 40 per cent. of cases operated on after this interval needed drainage. Expectant treatment was not so successful in children.

Mr. ADAMS, in reply, said that of 9 cases which died after expectant treatment, 3 died of general peritonitis, 3 of small bowel obstruction, and 3 of subphrenic abscess. In reply to the President, he said it was impossible to tell accurately what was happening inside the abdomen except at operation. If expectant treatment were generally adopted by hospitals there was a danger that the practice would extend to those treated elsewhere, whereas expectant treatment should only be adopted when the case was under the constant supervision of the surgeon who would, if and when necessary, operate.

### IMMUNIZATION AGAINST TUBERCULOSIS.

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland held on March 27th, the President, Professor J. T. WICHAM, in the chair, Dr. NATHAN RAW read a paper on the immunization of animals and man against tuberculosis.

Dr. Raw maintained that the protection of the human race and cattle by some safe and scientific method of active immunization was the only effective way by which this preventable scourge could be eradicated. Cattle, being susceptible only to bovine infection, could be protected more easily than human beings, who were susceptible to infection by both human and bovine bacilli, though not simultaneously. The vaccine he had used in his endeavour to immunize cattle was prepared from cultures of human tubercle bacilli which had been attenuated by monthly subculture during the last eighteen years. The present cultures, representing the 216th generation, were still true to type, but even when injected in large quantities into animals were non-tuberculo-genic and avirulent. Nearly all calves were born free from tubercle, and it was possible to give them sufficient immunity to resist ordinary infection. He had up to the present vaccinated over two hundred pedigree calves. The first injection of 0.025 mg. of human bacilli, previously killed by heat, was given at the age of one week, and the second injection at the end of the second week; almost all of these calves were negative to the test with Pasteur's tuberculin during the last two years. He could not say how long the immunity would last. The problem of immunizing children was more difficult, but during the last seven years he had treated over four hundred children, each of whom had a tuberculous parent, with two doses of bovine vaccine. Sufficient time had not elapsed to express any opinion as to its value. The vaccine, being prepared from dead attenuated cultures, was quite harmless, and gave rise to no reactions.

Sir JAMES CRAIG was particularly impressed by Dr. Raw's remark that there could be no hope of reducing the amount of tuberculosis in the country until better housing conditions were introduced, with better food and clothing for the poor.

Sir JOHN MOORE referred to the danger in the consumption of dairy milk, owing to the mixing of the milk from various farms, and emphasized the importance of the duties of the medical officers of health.

Professor J. E. CRAIG said that in Ireland only a half-hearted attempt was being made to check the disease in cattle. At present the aim of the Tuberculosis Order in Ireland was not so much the control of the disease in cattle as the prevention of its transference through milk to human beings. Unfortunately this Order was not being rigidly enforced, and milk infected with tubercle bacilli was often sold to the public. In England attempts were being made to get tubercle-free herds; but even this did not benefit poor people, for the milk from these herds was sold at a higher price than other milk. He felt that the object of workers should be, not to immunize cattle to disease,

but to eradicate it. In America and Canada some progress had been made. Although good results had been obtained experimentally by immunization the results in the fields had not been good. Von Behring had prepared a vaccine from human bacilli, and in his experiments good results had been obtained. Animals inoculated with this vaccine only remained immune while the organism continued in the body, and therefore an animal which was tubercle-free while a calf was liable to contract tuberculosis when a cow, and to convey the infection to its milk. Immunity apparently depended on the retention of living tubercle bacilli in the body. In Great Britain the use of vaccines had been employed on a fairly large scale, with the object of eliminating tuberculosis in cattle, but the results obtained by these vaccines were quite different from those of Dr. Raw. It seemed to him that vaccination in connexion with immunity had not yet gone beyond the experimental stage; he hoped that in the future preventive vaccination would succeed, and that calves, even of tuberculous animals, kept under ordinary conditions, would remain free from the disease. This would remove a great deal of the expense and trouble with which dairy farmers were at present faced.

Dr. W. D. O'KELLY said that in countries where the dairy industry was well developed about 50 per cent. of the cattle were tuberculous. In order to stamp out bovine infection in human beings he thought it would be necessary to sterilize all milk. Men, oxen, fowls, and monkeys were most susceptible to tuberculosis; pigs were less susceptible, the disease only occurring in about 3 per cent., and it was the same with sheep and goats: The endothelium of the lung was very susceptible to infection by tubercle bacilli, and in rabbits inoculated with the human bacillus the first parts infected were the lungs and the kidneys. Then, if the animals survived long enough, the joints became infected. The lungs of the ox could be to some extent infected with human bacilli, and if large doses of human bacilli were given to an ox it might die. An ox, when infected, developed an acute attack, but generally, if it overcame this, it survived. Tubercle bacilli were not found in the muscles, and the salivary glands usually escaped, but in 80 per cent. of tuberculous pigs the salivary glands were involved. He did not think the bovine bacillus was the common organism in the joints and bones; young children were perhaps more liable to an infection of the joints and bones than adults, since in adults the bones were more mature. He did not see why, if the vaccine was avirulent and non-toxic, the animals to which the vaccine was administered must be free from tubercle bacilli; he thought this was contrary to the experience of other observers. If the organism was non-toxic and avirulent, what sort of an antibody did it produce? Why could not living attenuated micro-organisms be given? He was glad to notice that Dr. Raw did not favour the transmutation of micro-organisms.

Professor JAMES WILSON said that when he was a student at Edinburgh Koch's tuberculin had been introduced, and great results were expected, but it was soon found to be not a cure for tuberculosis, though a very good diagnostic agent. Some years ago, on his father's farm, there had been a suspected case of tuberculosis in a cow, and by the use of the tuberculin test seventeen cows out of a herd of forty-five were found to be tuberculous, as well as a yearling heifer. Very few of the cows, however, had the udder infected. The infected cows were isolated, and those with healthy udders were allowed to suckle their calves. The premises were thoroughly disinfected, and at the end of the year all the calves were found by the tuberculin test to be free from infection. In some cases the infected cows continued to react to the tuberculin test for upwards of five years, but none of the calves treated on this plan were infected. A similar experiment in two farms in Aberdeenshire gave similar results, and pointed to the great importance of a thorough disinfection of the byres. The two most important things in connexion with the disease in cattle were thorough disinfection and separation of the infected cattle from the non-infected.

Professor J. W. BIGGER said that in a series of fifty Dublin specimens of milk which he had examined he

found that four contained tubercle bacilli. Diseases could be put into two classes: (1) self-curing, such as diphtheria or scarlet fever, the survival from which usually conferred complete immunity; and (2) those which were not self-curing, such as tuberculosis and syphilis. Tuberculous patients might improve, but after some time they usually became ill again and died. This fact was rather depressing when considering the possibility of curing the disease. Calmette, in France, had acted on the assumption that immunity could not be produced without injections of living tubercle bacilli, and had obtained some very good results. This method was very suggestive in view of Pasteur's original work on anthrax. Dr. Raw had referred to the antagonism between the human and the bovine bacillus, and said that if a child contracted bovine tuberculosis from milk it would not develop human tuberculosis. This was a most pernicious doctrine. There was considerable difficulty in isolating human and bovine bacilli from the same patient, but it was not right to say that the two types could not coexist in the body.

Mr. NORRIS said that undoubtedly tuberculosis was the most serious scourge with which veterinary surgeons had to contend. During the last forty years various methods had been adopted for the treatment of this disease in cattle, but they might all be classed as unsatisfactory up to the present time. Sometimes a herd was tubercle-free for a long time, and then suddenly some of the herd became infected again. In America tuberculous cattle were slaughtered, and the State paid compensation for such animals. By this method quite good results were obtained, but it was too expensive for use over here. In some parts of the country the Tuberculosis Order was strictly enforced, but in others not; vaccination had been practised for a long time, but he thought it had been a failure. Dr. Raw had vaccinated some two or three hundred calves, but had not used control animals with them, and the only way he tested them was with tuberculin after several months or a year, and so far no reaction had been noticed. It was a pity that the animals had not been inoculated with virulent material, and also that they were not controlled, in order to test the results; he saw no other way of arriving at a conclusion. Much good would result from the co-operation of medical practitioners and veterinary surgeons in connexion with tuberculosis amongst animals.

### LATERAL HEMIANOPSIA.

A MEETING of the Devon and Exeter Medico-Chirurgical Society was held at the Royal Devon and Exeter Hospital on March 26th, the President, Mr. R. WORTHINGTON, in the chair.

Dr. R. N. CRAIG showed a married woman, aged 28, a nullipara, who for five years had suffered from a variety of symptoms. There was no definite history beyond influenza, worry, and family bereavement. There had been transitory occipital headache, some paresis of face, also transitory, and right lateral hemianopsia. She was depressed and inclined to be hypochondriacal, but without morbid impulses; the memory was poor. The hair was thin, the scalp dry, and the individual hairs shortened. She suffered from chilblains in both feet, and the glucose curve showed variations from the normal; there was dulling of the previously normal sexual life. Dr. Craig considered that there had been improvement under treatment with calcium lactate and parathyroid.

Dr. RANSOM PICKARD considered that transitory hemianopsia was frequently related to a localized transitory oedema of the brain. He had seen a somewhat similar case in a girl responding likewise to calcium lactate. Dr. F. A. ROPER remarked that no one particular endocrine deficiency could be assigned as a cause for the deficiency and that it would seem that the ovary, pancreas, and thyroid could be equally arraigned. Dr. CRAIG, in reply to the President, said he considered that parathyroid intensified the action of calcium lactate. He was about to employ pituitary also in this case.

Mr. NORMAN LOCK showed a lad, aged 21, who had sustained a compound fracture of the right humerus, together with extensive burn of the arm, the injury having

of a printing press. Excellent progress had been made with local applications of chlorinated eucalyptol and paraffin. There was still stiffness at the elbow-joint, but the raw surface was now fit to take a graft.

Dr. SHAW read notes on the case of a boy, aged 14, in whom a large swelling of the humerus was stated to have followed almost immediately on a fall on the hand during a game of skittles. A radiogram showed what seemed to be a myeloid tumour of the humerus. Dr. Shaw excised the myeloid area of the bone and rejoined instead of grafting. Sections of the tumour indicated the condition known as osteitis fibrosa. Discussing this case, Mr. B. DYBALL referred to the recent work of Mr. Elnslic, whose cases ranged from blood cyst of bone to true myeloma. In Mr. Dyball's opinion the case before the meeting closely approached to myeloma.

Dr. MILLER MUIR read notes on, and showed skiagrams to illustrate, a case of large tumour in the left sacral region with slight extension over the middle line. The case had been greatly relieved by x-ray treatment, although, as regards the calcified portion of the tumour, there was diminution in area.

Dr. J. M. HENDERSON described eleven cases of dysentery occurring recently in the Devon County Mental Hospital. In six of these a positive Flexner reaction was obtained, and his results had been confirmed by Dr. R. SOLLY. A Shiga organism had been isolated, but agglutination was negative. Dr. Henderson showed the lower part of the ileum from one of these cases, the ulcerative process confining itself to the small intestine.

Mr. DYBALL read notes on two cases: (1) A girl with a twisted Fallopian tube. (2) A boy admitted to hospital with ruptured spleen, the interest being that the direct violence causing the rupture was delivered at the fifth left intercostal space—unusually high for this injury.

Dr. SOLLY read, in association with Mr. DYBALL, a short paper on malignant disease of the testicle illustrated by a case of carcinoma recently operated upon by Mr. Dyball. Dr. MILLER MUIR thought that the outlook was not good from the point of view of x-ray treatment in those cases where there was glandular infiltration above the groin.

### INDUCTION OF PREMATURE LABOUR.

At a meeting of the North of England Obstetrical and Gynaecological Society at Liverpool on March 20th Miss M. H. F. IVENS (Liverpool) read a paper on the induction of premature labour, a record of seventy-two consecutive cases.

Miss Ivens, after a brief historical reference to the introduction of this procedure, and to the changes in method introduced at various times, discussed the propriety of the operation, more especially in cases of minor pelvic contraction. Williams thought that the operation had lost popularity in America owing to the high foetal mortality. Statistics by Ahlfeld, Bar, Leopold, and Pinard showed a foetal mortality of 12 to 45 per cent.; they held that the operation was no longer justified, and that equally good results for the mother, and far better results for the child, would be obtained by subjecting the patient to the second stage of labour and resorting, if necessary, to Caesarean section. Kleinwächter thought the operation should be abandoned except when the child was abnormally large or there was undue prolongation of pregnancy. In the Queen Charlotte's Hospital records of 10,000 labours there were 206 inductions; there was no maternal mortality, but 26 infants did not survive, a 12.6 per cent. foetal mortality. Professor Briggs had recorded, in 1922, a series of bougie inductions in minor degrees of contraction with an 8 per cent. foetal and neonatal death rate. Most authorities believed that the child required greater care than a full-time child, and that the ultimate chance of life of the premature infant had to be carefully considered. Prophylactic induction was most likely to be successful when pregnancy had reached the thirty-sixth week and the conjugate of the brim measured at least 3½ in. Some thought labour should not be induced in a first pregnancy, but with a history of previous difficulty or loss of the child induction might be performed. The proper time had to be

determined by the estimation of the relation between the size of the pelvis and that of the foetal head, and the operation performed as soon as there was difficulty in pushing the head into the pelvis. A general anaesthetic was given and the vagina was douched with 1 in 2,000 mercury bichloride lotion; a toy balloon (as recommended by Professor Lowry of Belfast) was introduced with bullet forceps through the cervix. The balloon could be boiled, and so the risk of sepsis was less than with a gum elastic bougie, which could not be so efficiently sterilized. The membranes were not ruptured, and the risk of this happening was small; there was no interference with a normally situated placenta. The toy balloon was easy to insert, and there was no need of preliminary dilatation; it was distended with not more than 16 oz. of sterile water introduced with a piston syringe; the tubing was tied, and a gauze pack was left in the vagina.

The present investigation comprised 72 consecutive cases (with the exception of one case reported elsewhere), which were under observation during the years 1923 and 1924 at the Liverpool Maternity Hospital and Maternity Home; 30 were primigravidae, 42 were multigravidae. In 65 cases delivery was effected naturally, while 7 were delivered by Caesarean section. In these 65 cases the average period of gestation was thirty-eight and one-fifth weeks. The average weight of the children was 6 lb. 12 oz., and the average length 19.2 in. The average time from induction until pains began was 2 hours 47 minutes in the primigravidae and 3 hours in the multigravidae, if two cases were excluded where this time was much prolonged (110½ hours and 183½ hours). The average time from induction until delivery was 29 hours 17 minutes. The indications were: a minor degree of pelvic contraction in 63 cases, post-maturity and large foetus in 6 cases, and maternal disease in 5 cases. In 41 cases there was a minor degree of general contraction, the diagonal conjugate averaging 4.4 in. In 22 cases there was a minor degree of flattening, the diagonal conjugate averaging 4.3 in. Natural delivery resulted in 52 cases, delivery by forceps was performed in 9 cases, breech extraction in 4 cases, and Caesarean section in 7 cases where the head remained above the brim when the cervix was fully dilated. All the mothers survived. There were 74 infants (twins born on two occasions); 72 were born alive. Of the two stillbirths one was a hydrocephalic monster, and the other had been a pelvic presentation in a primigravida in which there was difficulty with the after-coming head. The neonatal deaths were due to (1) meningitis (fourth day), (2) diarrhoea and vomiting (twelfth day). All the infants but 4 (5.4 per cent.) left the hospital alive. Of the 70 living infants 58 had been traced, of whom 55 were alive, 3 having died in the first year. Only one case was complicated: delivery had been effected by high forceps, and the temperature remained high for a few days, but ultimately this patient made a good recovery. Miss Ivens claimed that by the induction of premature labour in suitable cases a considerable amount of suffering from prolonged labour due to minor pelvic contraction might be avoided, and she believed that this operation was not so inimical to the child as published statistics maintained.

#### *Operative Treatment of Chronic Endocervicitis.*

Dr. J. W. BURNS (Liverpool) read a note on the end-results of the operative treatment of chronic endocervicitis. The operation, which he had described to the society in 1922, consisted in the removal of the eroded area of the cervix together with the lower half or two-thirds of the cervical canal—namely, the infected portion—as devised by Sturmhorff. The immediate results were excellent—the vaginal discharge, haemorrhage, and profuse leucorrhoea disappeared, and the patients' general health rapidly improved. To investigate the effect of this operation upon subsequent conception, pregnancy, and labour, Dr. Burns collected cases which had been operated upon during 1922 and 1923, and endeavoured to follow them up. The total number of cases in which pregnancy might have been expected to occur was 65. Of these, 14 became pregnant within a period varying from two months to two years following the operation (21.5 per cent.). The average age of these patients at the time of operation was 35 years. Of the

14 patients 1 became pregnant twice within the two years, and 13 once, so producing 15 pregnancies; of these 15 pregnancies 10 went to full term, 3 terminated in miscarriage, and 2 were expecting confinement. Labour in the 10 at full term was natural. In 9 of the 14 cases dealt with there had been periods of sterility varying from two to eight years preceding the operation. Dr. Burns held that not only did the operation bring about rapid and permanent cure of the endocervicitis, but also that it had little effect in preventing conception, and that a normal labour might be expected at full term.

#### *Disease of the Urethra.*

Dr. W. FLETCHER SHAW (Manchester) described a case of double urethra with an epithelioma arising from one orifice. The patient, 42 years of age, had had recurrent flooding during the last four years. Dr. Shaw found she had a retroflexed uterus with a hard polypus half-way up the vaginal wall. Under an anaesthetic no malignancy was found in the body of the uterus or cervix, but an epithelioma, the size of a threepenny piece, was discovered on the anterior edge of the urethra. About half an inch to the right of this urethral orifice another opening was found, when a probe was passed through it, to enter the bladder and meet the other urethra, half an inch from the surface.

Dr. D. DOUGAL (Manchester) read notes of two cases of acute prolapse of the urethra occurring in elderly women. In each the onset was sudden, with acute pain and the desire to micturate frequently. In one case a small amount of blood was passed for a few days. On examination each presented a dark red swelling protruding from the urethral orifice, and it was thought that a carcinoma of the urethra might be present. Under anaesthesia the prolapsed portion was removed by circular incisions and the edges of the skin and mucous membrane brought together with catgut sutures; in each case the recovery was good. Histological examination showed that there was no malignancy, but that the tissue consisted of urethral mucous membrane with 'extensive haemorrhage' and thrombosis. Acute prolapse of the urethra was generally met with in children and elderly women, and only occasionally in women during active middle life. Senile changes caused shrinkage of the vulval tissues, and the urethral orifice became more relaxed and the connexions of the mucous membrane less secure. The diagnosis was usually easy, and treatment, as in these two cases, had given the best results.

Mr. MILES H. PHILLIPS (Sheffield) described three cases of prolapse of the urethra. The first occurred in a girl of 8, and was apparently caused by riding an adult's bicycle; the second, in a unipara of 26, three months after a confinement; and the third in a spinster of 56, who had had symptoms of chronic urethritis for some years. In all three cases the oedematous prolapsed mucous membrane was nearly an inch in length. Excision and restoration of the mucous canal was effected as Dr. Dougal had described.

#### *Clinical Cases.*

Dr. D. DOUGAL (Manchester) showed a specimen of primary carcinoma of the vagina removed from an unmarried woman, aged 26, who had had two children, the second two years previously; the only symptom was irregular haemorrhage of three weeks' duration. The specimen consisted of the uterus, appendages, and upper two-thirds of the vagina. The vagina contained a large fungating growth arising from the posterior wall, and reaching to the posterior lip of the cervix; histological examination showed it to be a squamous carcinoma. Its removal was easy as the growth was not adherent to the rectum in any way. Dr. Dougal also showed a pyometra associated with submucous uterine fibroids. The specimen consisted of the uterus and appendages removed by total hysterectomy, from a patient aged 55, six years after the menopause. The cavity of the uterus was dilated and filled with a large quantity of stinking pus. In the neighbourhood of the internal os were two pedunculated submucous fibroids, which had evidently blocked the cervical canal and led to the retention of the uterine secretions.

Dr. W. FLETCHER SHAW (Manchester) reported a case of normal pregnancy and labour after removal of twenty-three fibroids by myomectomy in a patient 40 years of age.

## Rebelsus.

### CANCER.

THE educational aspect of the cancer problem is dealt with in two books we have recently received—one by a past President of the British Medical Association, Mr. C. P. Childo of Portsmouth, and the other by Mr. H. W. S. Wright of Shantung, China.

Mr. CHILDE's book is entitled *Cancer and the Public*,<sup>1</sup> and is dedicated to the public. His object is to explain in simple language what surgeons and scientists know about cancer, and to emphasize the fact that thousands of lives are lost each year because patients suffering from cancer do not consult a doctor early enough. In 1906 he wrote a book, one of the earliest of this type, called *The Control of a Scourge, or How Cancer is Curable*, which was so much appreciated that Mr. Childe was pressed to address himself once more to the general public. The second book, still inspired by the same aim, is a fuller exposition of the subject under a new title. The reason for this change of name is evidence in itself that educational propaganda is bearing fruit, for Mr. Childe tells us that he had chosen the title "Cancer and the Public" for his former book, but the publishers were unwilling to agree to this, because, they said, the public would be afraid to read it. That was in 1906: in 1925 it appears that publishers show less timidity, and are not adverse to the author's choice of title. We predict that *Cancer and the Public* will not be handicapped, but rather prospered, by its outspoken designation.

Mr. Childe has proved by his arresting statistics that a book such as this is needed. In the chapter on the conditions of cure of cancer he takes each manifestation of malignant disease, and, quoting the figures of different hospitals, illustrates what a high proportion of patients with cancer only seek surgical aid when the time for surgical cure has passed. Thus, speaking of cancer of the rectum, he quotes the figures of St. Mark's Hospital, London, which prove that 83 per cent. of cases of cancer of the rectum are inoperable when first seen by the surgeon. We find but little more enlightenment amongst the non-hospital class, for an eminent rectal specialist in London admits that 50 per cent. of his private patients suffering from rectal cancer, when first seen, have passed beyond the stage when surgery can hold out any hopes of cure. Similar figures are given for cancer of other regions of the body.

Mr. Childe hopes that his words will reach to his medical and surgical colleagues also. How far have doctors done their duty by telling patients what medical science has discovered about cancer, by educating them to its earliest signs, and by warning them of the dangers of delay? The majority of the profession are acquainted with the ideas presented in such compelling fashion in this book, but the author declares "that there is not sufficient general conviction to impart the necessary 'ginger' to get a move on." Mr. Childe's missionary enthusiasm is calculated to "ginger up" the most Laodicean practitioner: it will also equip a new recruit with an aggressive armamentarium of facts and figures for a local educational campaign.

The other book, *The Conquest of Cancer*,<sup>2</sup> by Mr. H. W. S. WRIGHT, M.S., F.R.C.S., is one of the little series of scientific essays, "To-day and To-morrow," and keeps company with *Daedalus*, *Icarus*, and *Callinicus*, to which we have recently referred. It aims at telling the public what it ought to know about cancer: this object the author may be said to have achieved, though he does not beguile us on the road with the flights of imagination and literary wiles which have graced preceding members of this little series of books. His argument leads up to the conclusion that—

"If all persons over 40 years of age were routinely examined every six months to see that they had not cancer, or a pre-

<sup>1</sup> *Cancer and the Public*. By Charles P. Childo, B.A., F.R.C.S. (L.R.C.P.E. London: Methuen and Co., Ltd. 1906. 2s. 6d. net.)

<sup>2</sup> *The Conquest of Cancer*. By H. W. S. Wright, M.S., F.R.C.S. (Intro.) Trench, Trubner and Co., Ltd. New York: E. P. Dutton and Co. 1924. 1 x 61. pp. 86. 2s. 6d. net.)

cancerous condition, and if these, when found, were promptly dealt with, then cancers of the rectum, tongue, lip, breast, skin, and uterus would cease to be the plagues they are at present."

Here Mr. Wright rather weakens his case by overstatement. Perhaps after reading this a few anxious people may direct their steps towards the consulting room, but the more robust will have neither time nor inclination for such a general inspection until led to suspect that something is amiss. What people need to know is how cancer begins, and the sort of apparently trivial things they ought to ask their doctor about. Mr. Wright's methods would fill the consulting rooms of the psychotherapist more certainly than those of the physician. We are bound to say also that the introduction by Dr. CROOKSHANK, which occupies more than a third of the book, strikes an alarmist note.

### THE PITUITARY AND PINEAL BODIES IN EARLY LIFE.

THE title of Dr. LEREBONNET's little book, *Les Syndromes Hypophysaires et Epiphysaires en Clinique Infantile*,<sup>3</sup> is one that perhaps requires a little explanation. It deals with the clinical conditions produced by disorders of the pituitary and pineal bodies, either tumour growth or abnormal functioning; and not merely in infancy but throughout the early period of life when growth is the dominating tendency, and when disturbance in growth can assume various and remarkable forms.

Dr. Lerebonnet is well qualified to deal with the subject, in that he has already contributed numerous and important papers to its literature. In the volume before us he gives a brief review of the present state of knowledge and opinion regarding the pituitary and the pineal glands. The subject has raised obscure and complicated questions, and a very large literature has now accumulated. But the author brings to his essay the characteristic French gifts of lucidity and order, and he has provided what is both an admirable introduction to, and a review of, the subject. Approximately the same space is devoted to the pituitary as to the pineal gland; in each subject we are given first an account of the anatomy and microscopic structure; this is followed by an account of the results of operative interference and removal in animals, and then at greater length we have a relation of the various clinical entities in the period of childhood and adolescence that have come to be associated with tumour growth and disturbed function of these glands. These clinical conditions are indeed rare, but are remarkable and interesting. The principal clinical features of juvenile acromegaly, gigantism and dwarfism, obesity with or without retarded sexual development, precocious puberty, and diabetes insipidus are described, and a few illustrative cases are cited where the clinical data were found on post-mortem examination to be definitely associated with morbid conditions of the hypophysis and epiphysis. Treatment, both operative and by glandular extracts, is also discussed.

### THE PUERPERIUM.

THAT a second edition of Dr. LONGRIDGE's little book, *The Puerperium*,<sup>4</sup> should be called for proves that it has fulfilled the purpose for which it was intended. The book is designed primarily to assist the inexperienced practitioner in the successful management of his puerperal patients, but the author also addresses much wise counsel to midwives. The book is full of useful little tips which, while they do not find a place in a textbook, are nevertheless of considerable practical importance, and his advice throughout bears the obvious stamp of much clinical experience.

The author very concisely covers the whole of the lying-in period, including the care of the infant, advice as to feeding, and so on. Incidentally, Dr. Longridge pleads for an extension of the actual lying-in period to include at least three weeks' rest in bed—a prolongation which,

<sup>3</sup> *Les Syndromes Hypophysaires et Epiphysaires en Clinique Infantile*. Par Dr. P. Lerebonnet. J. B. Baillière et Fils, 1924. (Imp. 16mo. pp. 112. 12s. 6d. net.)

<sup>4</sup> *The Puerperium*. By Dr. J. B. Longridge, M.D., Ch.B. (Vict., F.R.C.S. Eng.). Second edition. London: Adlard and Son and West Newman, Ltd. 1924. (Cr. 8vo. pp. ix + 280. 6s. 6d. net.)

though having much to recommend it, will not, it is to be feared, make such a wide or attractive appeal to the mothers as it might to their attendants. The advice given is thoroughly sound and eminently practical throughout, and should prove of great service to those for whom it is intended.

### NEW BOOKS ON CHEMISTRY AND PHYSICS.

RECENTLY we have received a number of books on chemistry and physics, some written from the purely scientific and some from the applied point of view. Amongst the former we note with pleasure that the important book by Professor HAAS of Vienna has been translated into English by Mr. T. VERSEHOYLE, and appears under the title of *Introduction to Theoretical Physics*.<sup>5</sup> As Professor DONNAN points out in his foreword, the time has passed when a scientific worker is adequately equipped with a book on "heat, light, sound, and a little electricity," garnished with nothing more piquant than quadratic equations. Dr. Haas's book is a masterpiece on the principles of mathematical physics. It is based on lectures delivered at the Universities of Leipzig and Vienna, the author's object being to combine classical and modern physics into one united whole.

The third volume of a *System of Physical Chemistry*, planned by Sir William Ramsay and Professor DONNAN, is a book by Professor W. C. MCC. LEWIS on the quantum theory. It is intended for advanced students of physics, and deals with some physicochemical applications of the principles of statistical mechanics. First published in 1916, the present third edition<sup>6</sup> has been entirely revised and largely extended.

*Elementary Physics*,<sup>7</sup> by Mr. G. STEAN, reader in physics at Guy's Hospital Medical School, is an introductory textbook for medical students and first-year university students. It is intended for use in connexion with a course of lectures, accompanied by practical demonstrations on the lecture table, for it leaves out practical details of the experiments described, on the ground that these should be learnt in the laboratory. The author has had several years' experience in teaching medical students, and this book should be very useful as a guide to the preliminary medical examinations.

*Outlines of Organic Chemistry*,<sup>8</sup> by Mr. E. J. HOLMYARD, of the science department of Clifton College, begins with history, methods of analysis, and elementary theory, passes on to more advanced theory, aliphatic compounds, and leads up to carbocyclic and heterocyclic compounds. It represents what the author is accustomed to teach senior boys and medical students; it is written in an interesting way and adorned with five photographs of illustrious chemists.

*A Manual of Practical Chemistry for Public Health Students*,<sup>9</sup> by Dr. A. W. STEWART, is a small book especially arranged for those studying for the D.P.H. Eleven years have passed since the appearance of the first edition, and the experience of this period has persuaded the author that nothing can be expressed too simply for the guidance of students. Dr. Stewart appears to have taken a good deal of trouble not to incorporate anything that is not absolutely necessary for the practical chemistry exercises of D.P.H. students.

The French textbook *Précis de Chimie Physique*,<sup>10</sup> written by Dr. H. VIGNERON, covers the whole ground of physical chemistry. Though not addressed especially to medical readers, this book would certainly be useful to doctors

or students looking for a straightforward account of the principles and laws of physical chemistry. The second volume of *Pharmacodynamic des Colloïdes*,<sup>11</sup> by Dr. W. KOPACZEWSKI, deals with protein therapy and the transfusion of blood. We group it under the head of books on chemistry and physics because the author concludes that the introduction into the circulation of different proteins always causes a disturbance of colloid equilibrium, especially in the blood cells. This conclusion is based, not on symptoms, but on an analysis of the biological modification of body fluids and their physicochemical properties. The book includes an extensive bibliography.

### ANNALS OF MEDICAL HISTORY.

The first article in the winter number of the *Annals of Medical History*<sup>12</sup> is by Dr. Eli Meschcowitz on the first editions of Sir Thomas Browne's works, and is well illustrated by portraits in the text and by one of the Knight of Norwich on the cover. The frontispiece of the number represents Samuel Thomas von Sömmerring (1776-1830), whose life and work are sketched by Dr. Theodore H. Bast of Madison, Wisconsin. Inspired in his student days by Wrisberg and Blumenbach with enthusiasm for research, von Sömmerring had great difficulty in inducing his father to supply him with funds sufficient for his education, but his successful thesis opened the paternal purse, and it is thought excited the jealousy of Wrisberg, who did not exert himself to obtain a professorship for his able pupil. However, after a visit to England, where in 1778 he sat at the feet of John Hunter in London and Alexander Monro in Edinburgh, he became professor of anatomy at Kassel, and five years later moved to Mainz, where he began a long friendship with Goethe; there he brought out his famous handbook on anatomy in five volumes, and incidentally a paper, which aroused much criticism, on "The Organ of the Soul," dedicated to Kant, who, though a great admirer of his previous work, had nothing favourable to say about this one. After vicissitudes due to the French occupation of Mainz, he settled for a time in practice at Frankfurt, and in 1805 became Geheimrat and member of the Academy at Munich, where eventually he ended his days in great honour. Lieutenant-Commander W. M. Kerr of the Medical Corps of the United States Navy describes the life of W. M. Wood (1809-1880), the first surgeon-general of his service, with numerous excerpts from his writings and letters. In his interesting biographical history of physical diagnosis Dr. W. S. Middleton traces the subject from Hippocrates to Austin Flint (1812-1886), who was called the American Laënnec by Samuel D. Gross. A scholarly article by Dr. M. A. van Andel of Gorinchem, Holland, on "The Ceraunia or Thunder-axe: its use in Folk Medicine," shows that prehistoric flint implements are still regarded in some parts of Europe as of celestial origin and due to lightning, and are believed to have curative properties. In an essay on "Rabelais a physician" Dr. Isador Coriat of Boston, Mass., contends that this unique genius, who was primarily a man of letters and a medical man by the way, represents our own uncensored selves, and that he wrote as he thought, whereas most people when writing are constantly censoring their conscious and unconscious thoughts on account of the external pressure of social repression and custom. Dr. Charles Greene Cumston, now of Geneva, contributes some historical notes on small-pox and inoculation, showing that at one time paralysis was a sequel of variola. Dr. W. G. Aitken Robertson's article on Andrew Boorde's *Brevariary of Health* contains some curious information and incidentally mentions that this sixteenth century author died in the Fleet Prison, to which he had been removed "on its being discovered that he had kept a brothel for his brother-bachelors." The last original article on the careers and contributions to science and education of the two Seguinis of New York, Edouard and Edward C., father and son, is by Dr. Charles L. Dana. This, the concluding,

number of the sixth volume of the *Annals of Medical History* contains most interesting material, and deserves, for its admirable printing, illustrations, and style, widespread support from medical readers.

### NOTES ON BOOKS.

DR. E. F. CYRIAX'S *Collected Papers on Mechano-Therapeutics*<sup>13</sup> are written in English, French, or German, and were contributed to various medical journals, sometimes jointly with Melville. These methods of manual treatment appear to have originated with P. H. Ling in Sweden about 1835, but were modified by Henrik Kellgren, of the Royal Gymnastic Central Institute in Stockholm, after he had settled in Gotha as a medical gymnast in 1869. According to Dr. Cyriax, it was Kellgren who assigned particular value to the mechanical treatment of the nerves, and extended the treatment to neurotic conditions for which Ling considered his own form of treatment unsuitable. Kellgren had a great vogue in the seroties and eighties of last century; he established an institute in London, and ultimately founded others at Norderney, Baden-Baden, and Paris. Dr. Cyriax has treated by Kellgren's methods many nerve diseases, affections of the bones and joints, displacements of the vertebrae and the ilium, constipation, high blood pressure, diabetes, some forms of heart disease, albuminuria, and polyuria, and influenza. His treatment appears to have resulted in almost invariably successful, but whether this may not have been due to particularly rose-coloured spectacles in the possession of Dr. Cyriax or his patients is not clear. The manipulations and vibrations used are very gentle, and no doubt from constant practice have become most efficient. But we have grave doubts about the routine treatment of pneumonia in this way; at all events, by anyone less skilled in the art than Dr. Cyriax. Apart from the feeling we have that in acute febrile conditions the patient dislikes being disturbed, we are doubtful of the physiological results enumerated by Dr. Cyriax. The book is profusely illustrated with many excellent photographs.

The fact that Professor H. A. HARE'S *Textbook of Practical Therapeutics* has now reached its nineteenth edition<sup>14</sup> is an indication of its well established popularity. The last edition appeared in 1922. The general arrangement of the volume remains unchanged, but the text has been altered extensively. The author points out in his preface that progress in therapeutics is much wider and more rapid than is generally realized, and remarks that the changes in the past three years have necessitated more extensive alterations and additions in his book than have been required in any previous edition. The first half of the book consists of brief descriptions of the pharmacological actions of many hundreds of drugs disposed in alphabetical order. The value of these summaries varies considerably, and some of the statements would not find general acceptance in this country. The section on remedial measures other than drugs is particularly interesting. The latter half of the book is an index of treatment of disease, and gives a short account of the treatment of all the chief diseases. The book is well illustrated with line drawings, photographs, and coloured plates.

The first volume of the second edition of the handbook of internal medicine, originally edited by Professor L. Mohr of Halle and Professor R. STAEHELIN of Basle, has recently been published in Berlin.<sup>15</sup> Professor Mohr died in 1918, and has been succeeded by Professor G. VON BERGMANN of Frankfurt as co-editor. Of the other contributors to the first edition a quarter have died. In the previous edition only one volume was devoted to infectious diseases, but owing to the great increase in our knowledge of this subject since 1911—the date of the first volume of the first edition—only twenty-three infectious diseases are discussed in the present work; the remainder are to be considered in the second volume. Professor F. Rolly of Leipzig and Professor E. Müller of Marburg, who are the only two surviving contributors to the corresponding volume of the first edition, have revised their

<sup>13</sup> *Collected Papers on Mechano-Therapeutics*. By Edgar F. Cyriax, M.D., Edin. London: John Bale, Sons and Danielsson, Ltd. 1924. (Cr. 4to, pp. xiv + 472; 125 figures, 12s. net.)  
<sup>14</sup> *A Textbook of Practical Therapeutics*. By H. A. Hare, B.Sc., M.D., F.R.C.P. Nineteenth edition, enlarged, thoroughly revised, and largely rewritten. London: Henry Kimpton. 1925. (Med. 8vo, pp. x + 1061; 153 figures, 8 plates, 36s. net.)  
<sup>15</sup> *Handbuch der inneren Medizin*. Zweite Auflage, herausgegeben von G. von Bergmann und R. Stachelin. 1. Band. 1 Teil. Infektionskrankheiten. Berlin: Julius Springer. 1925. (Roy. 8vo, pp. xii + 717; 232 figures, G.M.45.)

articles on the acute exanthemata and epidemic poliomyelitis respectively. A new section in the former article is devoted to erythema infectiosum. Professor R. Massini of Basle contributes the chapters on influenza and herpetic fever, which were formerly the work of Professor P. Krause of Bonn. The articles on whooping-cough and mumps, which were also previously written by Professor Krause, are now from the pen of Professor M. Klotz of Lubeck. The chapter on diphtheria, previously written by Professor Krause, has been entrusted to Professor F. Göppert of Göttingen, who is also responsible for the chapter on cerebro-spinal fever, which had previously been written by Professor Jochmann. The chapter on cholera is now the joint work of Professor H. Elias of Vienna and Professor K. Doerr of Basle. The new articles in the volume are those on epidemic encephalitis by Professor Stachelin of Basle and Professor W. Loeffler of Zürich, and on infectious jaundice, trench fever, and serum disease and anaphylaxis by Professor A. Schittenhelm of Kiel, who also deals with tetanus and typhus fever, previously discussed by Professor Krause, and with the dysentery, for which Professor Jochmann was previously responsible. The book, which is well printed and illustrated, will be found useful for reference by those familiar with the German language.

### MEDICAL AND SURGICAL APPLIANCES.

*Nitrous Oxide Inhaler.* Mr. FRANKIS EVANS writes: The apparatus illustrated is a modification of Paterson's nose-piece for the administration of nitrous oxide. The nose-piece is the same shape as the original, and has a wide and deep rubber pad. In my experience it fits noses of all shapes very well. The mouth-piece is connected to the nose-piece by a stout rubber tube, and can be swung round to the back. This movement cuts off the supply of gas to the mouth-piece by closing a valve at the top of the nose-piece. When not in use the mouth-piece rests on the head-rest of the chair, and the whole apparatus is then held quite firmly to the nose by the weight of the gas-piece hanging behind. On the nose-piece is an expiratory valve of the hairspring type, which does not stick as the rubber flap type may.

A rebreathing position is afforded by turning the tube carrying the expiratory valve through an angle of 45 degrees. The apparatus has been made by Messrs. Coxeter and Son, Ltd., 171-175, Finsbury Road, N.W.1.

*Urethral Irrigators.* Mr. W. K. IRWIN, surgeon to out-patients, St. Paul's Hospital, for Genito-Urinary Diseases, writes: The irrigator depicted differs slightly from those in ordinary use. Its main feature is the shape of the stem, which is curved instead of straight. The curved stem forms a convenient handle, and the instrument is so much easier to use than those of the ordinary type that it is difficult to believe that, as I am told, it has not been made before. Further advantages are that the curvature prevents the irrigator from rolling about when placed on the table and minimizes the risk of the rubber tube kinking at its junction with the metal part. Extra elevation of the container will readily compensate for any loss of force in the stream due to the curve. This makes it easy to remember which position is "on" and which is "off." Both the shield and the nozzle fit tightly on to the stem, but are easily removable for sterilization. The nozzle can be inserted into the funnel-shaped end of a gum-elastic catheter, so that the instrument is convenient for washing out the bladder. It has been made in accordance with my instructions by Mr. Montague of New Bond Street.

*An Arm-sling.* The Euphoros arm-sling has been designed by Miss I. M. RANGLER to obviate the strain on the neck caused by the usual form of arm-sling and to allow the maximum amount of freedom to the elbow and shoulder-joints, while giving perfect support to the forearm. A curved back-piece is attached to a waist belt. Straps of webbing start from its upper points, and, passing over the shoulders, are connected by buckles with the sling for the forearm, which can thus be easily adjusted to the required height or angle by the patient himself. The sling has a perfectly level base; a gusset at the elbow covers the end of the splint, and rest for the arm is obtained without the sense of carrying weight. It is made of a light and durable black material, and can be obtained from Squire and Sons, Ltd., 413, Oxford Street, London, W.1, price 10s. 6d.

## Nova et Vetera.

### LIMBS AND BRAIN.

THE consideration in the JOURNAL last year (January 12th, 1924, p. 79) of the case of a man without arms, and of the success with which the legs and feet may be trained to take on themselves the functions of the missing limbs, prompts the question to what extent and in what manner life is possible for individuals born without limbs of any sort, or possessing, at the most, rudimentary stumps too short and too little differentiated to be prehensile. An answer to this question is contained in the very full and active life of the Right Hon. Arthur MacMurrough Kavanagh, M.P., who took a considerable part in the public affairs of his time, and whose remarkable achievements surpassed even those of Ducornet (a pupil of Watteau), to whom reference is made below in the note on Mrs. X—. The following brief account of Mr. Kavanagh will give some idea of the manner in which he overcame his physical disabilities.

#### MR. ARTHUR M. KAVANAGH.

Born with the merest rudiments of limbs, Mr. Kavanagh overcame every difficulty that presented. At the age of 16, strapped upon the saddle of his horse, he rode a long tour through the Near East. His elder brother, who accompanied him, writes home: "Arthur shoots much better than Mr. Wood, who began about the same time that he did, and can hit a bird flying quite well. His shooting is quite as wonderful as his riding. He is the only one of the party who can speak Arabic, which he does perfectly." (*Life of A. M. Kavanagh*, Macmillan and Co., 1891, p. 26.) Later on in India he shot tiger. At 23 years of age he succeeded to the family estates, and in the next year, 1855, he married. When 37 years old he was returned to Parliament as member for County Wicklow. In the troublesome Irish politics of his day he played an important part until his death in 1889. His *Life*, published two years later, is reticent as to his physical disabilities and the means by which he overcame them. Of his childhood nothing is told us in detail. His friends and intimates are now a diminishing band. Mrs. Rees-Mogg, who as a young girl knew him well, has been good enough to send us the following reminiscences:

"Mr. Kavanagh was the fourth son. He married a cousin. He rode up most days to see my people at Mt. Leinster. He had a sort of seat like a chair strapped to the horse. He held the reins wrapped round his arm. One arm was a little longer than the other, finishing a little below the elbow-joint; the other arm was thinner and smaller and ended above the elbow. He held the whip under one arm and the reins were twisted round the other. He wore a long skirt, and his legs did not come as far as the knee. I rode with him often, and sat behind him on the horse, holding on to the belt which he had round him somehow attached to the reins. Of course, I rode sideways.

"He wrote putting his two stumps together and so held the pen, taking it between his teeth to dig into the ink.

"Every morning when you came down there was Mr. Kavanagh sitting by a table in the window with a Bible before him, and read prayers. He used to jump on to his servant's back, who stooped for him to jump on to. He used to help the soup at dinner and pour out the coffee at breakfast. He was so absolutely charming and attractive that all the young lady guests used to fight as to who should sit next him. My sister and I and a friend went on a tour with him on his yacht the *Era* (about 230 tons), which he always steered himself, being his own captain. He had his own servant with him. He used to push himself about on the clean deck on his stumps. We went to Corfu for four months. He had an aunt there who had married a Greek. Mr. Kavanagh took photographs, which he did very well. We also went to the Adriatic."

We are also indebted to Mrs. Rees-Mogg for the loan of a valentine that Kavanagh sent her when she was a child. The valentine is of quarto size, and the first page is printed on lace paper. It contains a picture of "love's barometer" mounted on satin, and assured the young lady that it was ever sunshine when she was near. On the second page Kavanagh had written some verses, of which the first two are here reproduced in facsimile. (The eagle's feather refers apparently to Kavanagh's pen.)

For many years he copied into the first page of each new diary a prayer for strength and Longfellow's "Psalm of Life."

"Let us then be up and doing,  
With a heart for any fate,  
Still achieving, still pursuing,  
Learn to labour and to wait."

It is probable that these cases are not quite so rare as would appear from the scanty records of medical societies and medical journals. If there were a literature of the circus and of the travelling show the total of "limbless wonders" might be found to be considerable. Stow, the chronicler, makes mention of a Dutchman who, with his two arm-stumps, could keep a cup in the air, throwing it from stump to stump like a juggler, and who could shoot an arrow.

MR. ARTHUR KAVANAGH.

Reproduced by permission of Messrs. Macmillan and Co. from "The Right Honorable Arthur MacMurrough Kavanagh," a biography compiled by his cousin, Sarah L. Steele. 1891.

*Oh bliss untold if Cupid's dart  
And not the Eagle's feather  
Had found a refuge in your heart  
I would then be sunny weather*

*Oh Lizzy could a hope appear  
That Love's Barometer wld rise  
To quell the fangs of jealous fear  
Show light before one's eyes*

Mrs. X—.

I have enjoyed an opportunity of making the acquaintance of the present-day representative of these limbless performers—Mrs. X—, 42 years of age. I am indebted to Dr. A. G. Phear for the introduction, and to Mr. Ulysses Williams for the x-ray plates here reproduced. Her infancy was very delicate, and it was long before she could sit up or pass beyond the stage of helpless dependence on others. From about the age of 8 she began to

make rapid progress. From the age of 16 she has managed all her own affairs, and made her own arrangements for the tours on which she exhibits her remarkable dexterity. She writes a clear flowing hand, makes her own clothes, knits, crochets, dresses her own hair, and threads the rings of her earrings in and out of her pierced ears. In the house she pushes herself up and down stairs without assistance, and is active in domestic work. The adductors of the arm-stumps are

of very great power, and the neck muscles similarly are much hypertrophied. The handiwork which she does with such pride and delight is accomplished with the two arm-stumps, each with a single projecting rudimentary digit, while meeting and opposing them, with innumerable rapid perfectly co-ordinated movements, are chin, lips, and sometimes tongue or teeth. The left arm is about six inches long, the right about four inches; the right leg ends about the knee, the left is a mere rudiment. The pen is held fast against the chin by the pressure of the left stump of arm, which is considerably more dexterous than the right, and the movement is imparted almost entirely by the action of the neck muscles. Watching the quick, clever movements of this woman makes less incredible the achievements of Watteau's pupil, Caesar Ducornet, who was born without arms and with only rudimentary legs; yet he carried off all the prizes at Lille, won gold medals at Paris, and had pictures at the Louvre.

#### CASES RECORDED IN MEDICAL LITERATURE.

The medical literature concerning such cases is strangely scanty. It is possible that some references have been overlooked, for search has brought to light only the following cases.

Hastings reports the case of a male child born with the merest rudiments of limbs, under the title "Description of a monster in whom the upper and inferior extremities were entirely wanting." Only in place of the left leg was there a rudimentary projection. "On the left side, at the part of the ossa innominata into which the head of the thigh bone is generally received, there is a little process in the shape of a finger, consisting of two small bones united by ligaments and covered with skin and cellular membrane. This projection has muscles attached to it, as it is constantly moved by the cries and struggles of the child. The projection is thick at the base and runs to a point, and there is a nail affixed to it." "The desire of the parents," says Dr. Hastings, "to derive pecuniary advantage by exhibiting this monstrous production has proved fatal to it. They carried the child to most of the towns in this neighbourhood and exhibited it to many hundred persons. In one of these excursions inflammation of the lungs came on and the child died." Its age at the time of death was 6 months. (*Trans. Med.-Chir. Soc. of Edinburgh*, 1826, p. 39.)

Garlick reports the case of a child which survived some time with stumps of limbs which did not exceed three inches in length. (*Provincial Med. and Surg. Journ.*, 1849, p. 279.)

A similar case was reported in 1853. The child, a male aged 6 weeks, had the power of moving the stumps freely and strongly. This case appears to have been the first in which it was suggested that there had been amputation during foetal life by means of constricting bands—either amniotic adhesions or the umbilical cord—in this case, as in that reported by Hastings, of a rudimentary toe. One speaker at the discussion alone addressed himself to this difficulty. The toe he regarded as an attempt at repair after amputation, and compared it with the formation of new limbs

after traumatic loss in crabs. (*Med. Times and Gazette*, 1853, p. 604.)

Mr. (afterwards Sir Jonathan) Hutchinson reported the case of a child with all limbs reduced to mere stumps, which was alive and well at the age of 2 months. (*Trans. Path. Soc. London*, vol. v, 1854, p. 343.)

Baker Brown exhibited a 3 months old child "with short stumps replacing both upper and lower limbs." (*Trans. London Obstet. Soc.*, vol. viii, 1865, p. 102.)

Cook reported the case of a living child with all four limbs reduced to merest rudiments. (*BRITISH MEDICAL JOURNAL*, June 14th, 1890, p. 1360.)

Weinlechner exhibited before the Medical Society of Vienna a man, aged 27, who was devoid of all extremities except that, on the right side, a small stump of the arm had permitted the adjustment of an artificial apparatus. He could write, thread a needle, and pour water from a bottle. It is probable that the man shown on this occasion was the well known Nicolai Wassiliewitch Kobelkoff, a celebrated performer in the circus at that time. He was born at Troizk in Siberia in 1852, a fourteenth child, all his brothers and sisters being normal. He married in 1876 and had five children; all of whom were normal. Kobelkoff had the rudiments of legs, one thigh being about six inches long, the other about two inches longer, but for a right arm merely a conical mound, and for a left a rounded projection representing the humerus. With these stumps he conducted an entertainment exhibiting in the different towns of Europe. He could fix a pin between his cheek and arm, and wrote a good clear hand. He could cut paper with scissors, pour water from a bottle into a glass, eat with a fork and spoon, take his watch from his pocket and open it, thread a needle, and fire a pistol. (*Ally. Wien. mcd. Zeit.*, January 22nd, 1878, p. 38. See *Day's Even Paper*, July 2nd, 1887, vol. ix, p. 637.)

Sarah Biffin, who, also showed herself at fairs, and whose name may be seen on one of the show boards in Rowlandson's picture of Bartholomew Fair in 1799, later also achieved celebrity as a miniature painter. She died in 1850. Recently one of her miniatures realized forty guineas at Pittick and Simpson's auction rooms (see *John o' London's Weekly*, November 8th, 1921).

The lessons to be drawn from such cases are obvious enough. The brain, so long as its quality is unimpaired, may achieve great results, however ill adapted seemingly the appliances with which it has to work. So long as somehow and by some means the body can achieve the mobility necessary to acquire and refine sensory impressions the loss of the specialized limb is compensated. It seems as if sensorimotor auto-education would be impossible only if we could suppose a state of limblessness combined with an ankylosis of the cervical spine.

The slightest cerebral defect or damage is productive of incapacity immeasurably greater than that entailed by the almost complete absence of all four limbs. Oliver Wendell Holmes declared that some special Providence watched over and inspired Helen Keller in her conquest of blindness and deafness. So with Kavanagh. The immensity of the difficulties of his task seems to have evoked and been balanced by a patience and perseverance equally great.

H. C. CAMERON, M.D., F.R.C.P.

Mrs. X.—: the rudimentary left humerus and digit.

Mrs. X.—: the rudimentary lower extremities.

## APPENDICITIS.

THE new year has seen a revival of interest in what has come to be regarded as a well worn subject—appendicitis. Mr. Rendle Short's lectures<sup>1</sup> on the subject have been quickly followed by Mr. Sherren's contribution and the address given by Mr. J. E. Adams before the Section of Surgery of the Royal Society of Medicine. Both are printed in the opening pages of this issue, and a report of the discussion which followed in the Section will be found at page 739. Some rather alarming figures of the numbers of deaths from the disease, and the suggestion that immediate operation is not certainly the best routine treatment for appendicular peritonitis, are the stormy petrels of the moment.

It is as perfectly clear as ever it was that immediate operation is the treatment of choice during the early stages of appendicitis—that is, while the condition is still truly one of appendicitis and not yet a peritonitis, or if that, only in its earliest stages and least degrees. We trust that there will never be any misconception on that point. Owing to individual variations the time at which the one merges into the more serious other is variable, but it may be taken that peritonitis is at a minimum in the earlier hours. When this stage has been passed a certain mortality begins to creep in. Even in the early groups there is a mortality of something under 1 per cent., rising in some series even to 2 per cent., of deaths in twenty-four-hour cases. These are the fulminating cases, or, if ordinary, certain unusual complicating circumstances account for the deaths. Allowing for the small percentage of error in diagnosis by skilled clinicians which must be reckoned on in any large series of cases, it is evidently within our power to lower vastly the death rate by operating on all cases of appendicitis within the most favourable period. Were this done we should not have lost 2,826 cases in 1923, and certainly not as many as 28,000 cases (the population of a country town) in the last ten years. When we remember that these dead were mostly young people we realize what this loss may have meant. Then we have to consider the working time lost and the expense to the hospitals and to the community which those cases requiring drainage and prolonged hospitalization cause. There is the added factor of abdominal walls weakened by incisional hernias, and so forth. The general practitioner cannot be blamed for all the delay before surgical assistance is sought, for in industrial and in country areas the generalized colicky abdominal pain which is the chief feature of the early hours is often not regarded as serious enough to warrant calling in the doctor. Too often it is not until the mischief has definitely located itself in the right iliac fossa that help is sought, and this change means that the case is no longer one of obstructive appendicitis but one of appendicular peritonitis. Mr. Sherren's remarks on the symptomatology of appendicitis are very sound, and should be memorized by all who are not already acquainted with these facts. Equally true are his sentences on chronic right iliac pain, which does not denote, as is so often thought, chronic appendicitis. The diagnosis of acute appendicitis is rarely difficult, and all doubtful

cases should be removed from their homes for skilled observation.

For those cases which have, for one reason or another, not been subjected to operation within the first few hours what are we to do? It is generally agreed that the mortality is highest in those patients on whom the operation is performed on the third day, and there is growing up in England a school—comparable to that of Ochsner of Chicago—which advocates starvation, morphine, and no purgation, in order to obtain absolute peritoneal rest. If the case settles down, appendicectomy is performed at the end of a week or two, when, it is hoped, a clean operation may be done with immediate closure. This late appendicectomy is not really part of the treatment of appendicitis in these instances, but is rather of a prophylactic nature. Indeed, this treatment of appendicitis is essentially, non-operative, with a reservation. The reservation is that if at any time the case does not seem to be settling down operation will be undertaken at the discretion of the surgeon. The statistics of the London Hospital and of St. Thomas's Hospital show that a large number of cases do not so settle.

It must be said at once that this treatment places a great responsibility on the shoulders of the surgeon. It should never be carried out at the patient's home, and if it fails, if the patient subsequently dies after a delayed operation, considerable unpleasantness may arise. Still, if it can be proved that a lowered mortality can be obtained by this method, obviously it should be adopted. Before we trust our judgment to the tender mercy of statistics we must be sure that the cases being compared are in truth comparable, that they are true scientific controls the one of the other. Certainly much larger series of cases are needed before we can be quite certain where we are. Similarly the fact that 2,826 people died from appendicitis in 1923 and 2,528 in 1913 does not necessarily mean that we are doing worse than we did ten years ago. It may mean that, but it does not necessarily mean that. No figures are available of the total numbers afflicted, and none could be so available unless the problem were thought serious enough to require compulsory notification of appendicitis. The one fact that is clear is that even to-day, after a quarter of a century of skilled treatment and of educational battalions of people are still dying . . . appendicitis.

Mr. Adams's objections to the "wait and see" policy are very pertinent, and we feel sure that it would be nothing less than a disaster if the method were to be employed generally out of hospital. If it is to find an established place for itself it will, we trust, remain a surgeon's treatment, a variety of institutional treatment, with a certain operation at the end of it. In other words, it is a form of pre-operative treatment, and not an end in itself.

## THE MORTALITY OF THE MEDICAL PROFESSION.

IN the *Journal of the American Medical Association* (January 10th, 1925) there appeared an interesting leading article on the deaths of physicians in 1924. Our contemporary estimated the number of practising physicians in the United States (the term "physician" is, of course, to be taken to cover all regular practitioners) to be 145,966, and, adding 2 per cent. to the recorded total to allow for possible omissions, put the deaths at 2,536, giving an annual death rate of 17.37 per 1,000. The average over the last twenty-three

<sup>1</sup> *Lancet*, January 31st and February 7th, 1925.

years is stated to have been 16.94 per 1,000. This latter figure agrees almost exactly with that deduced from the Registrar-General's Occupational Mortality Supplement, which deals with the experience of England and Wales in 1910-12. In these three years 1,246 registered practitioners (physicians, surgeons) died, and this, brought into relation with the number exposed to risk, 73,659 (three times the enumerated population at the census), gives a rate of mortality of 16.92 per 1,000. The rate in America in 1924 was slightly worse than ours a decade ago, but the fact that five physicians were killed by bandits suggests that the practice of our art in the United States may be somewhat more hazardous than here; that ten of the deceased physicians were bank presidents is perhaps evidence that it may also be more lucrative.

We publish in this issue an analysis by Mr. A. B. Hill of the mortality amongst English physicians of a bygone age, the word "physician" being here used in a restricted sense—namely, of Fellows and Licentiates of the London College of Physicians admitted at least a hundred years ago. The longevity of these old-time doctors is much superior to that of all medical practitioners in our own age, and compares favourably with that of married peers of the realm in their own age; Dr. Brownlee has kindly permitted Mr. Hill to quote the data about the peers from unpublished material. In the current issue of the *Proceedings of the Royal Society* (Series A, vol. 107, p. 368) Sir Arthur Schuster has estimated the expectation of life of Fellows of the Royal Society from the data of the last seventy years. Taking as an example the expectation of life at the age of 45, we find that Sir Arthur Schuster reaches for Fellows of the Royal Society 28.4 years; Mr. Hill obtains for physicians born between 1750 and 1799 27.2 years, and Dr. Brownlee obtained for peers 26.0 years. Mr. Hill deduces from the experience of 1910-12 for all medical practitioners 24.7 years, and the value in English Life Table No. 8 (all males, experience 1910-12) is 23.9 years.

The bearers of the gold-headed cane come very well out of this comparison; they were, indeed, a little worse off than those who have surmounted the intellectual obstacles which have, since the number of admissions was limited, guarded the portals of the premier scientific society; but, having regard to paucity of numbers and differences in method of calculation, one cannot put much weight upon the difference. On the other hand, it is improbable that the advantage of the physicians of a hundred years and more ago over all practitioners of our time is illusory. Something must be allowed for age selection—the average age on admission as a candidate or licentiate was certainly higher than the average age of registration now; something for social class—all the Fellows in the eighteenth and most in the other centuries were graduates of Oxford and Cambridge; but, having regard to the results in the peerage, these can hardly be the whole explanation. Perhaps the truth is that the more leisured life of a physician in the eighteenth century—he probably indulged less than his lay contemporaries in the vice of hard drinking—was a quite sufficient makeweight for the superior scientific resources of his twentieth century brother in general practice. One wonders whether an investigation such as Mr. Hill has made, if extended to Fellows and Members of the Royal College of Physicians of the last fifty years, would produce similar results, and substantiate a claim for a reduction of the life assurance premiums of those who have satisfied the Censors' Board.

#### THE NATIONAL PHYSICAL LABORATORY.

The activities of the National Physical Laboratory for 1924 are reported in a stout quarto volume.<sup>1</sup> The greater part of the research carried on at Teddington is not of a kind from which conclusive results can be expected within a particular year. Work on various international standards and scales, or along lines of research which require prolonged investigations to be repeated for one material or one set of conditions after another, has necessarily to be continued over a period which may be represented by several annual reports. While there is much to interest the reader of a scientific bent of mind in these 200 pages, there is very little in the way of absolute conclusion to be winnowed out. The mills of the National Physical Laboratory "grind exceedingly small." It is hoped next year, however, to complete the work, which has been proceeding for some time, on x-ray protective materials, and in this connexion it is noted that recommendations on somewhat similar lines to those established by the laboratory have been drawn up by protection committees in America and in France and Germany and some five other European countries. Most of the work of the laboratory, so far as x rays are concerned, has been on spectrometry and other questions falling under the head of what is called "atomic physics," but the x-ray departments of a number of hospitals have also been inspected, and advice has been given on the equipment of proposed new departments. The new x-ray apparatus submitted for inspection show marked improvement both in construction and in the protection afforded. Preliminary experiments have been made with cathodes of various curvatures with a view to the design of an x-ray tube capable of passing extra heavy currents and of withstanding increased potentials. Radium testing has become a routine procedure at the laboratory, and institutions in which radium is in constant use are sending their tubes and applicators periodically to the laboratory for examination for leakage; 111 tests of radium preparations were made during the year. Apart from work on x rays and radium, the report touches here and there on matters of medical interest, although these matters are few in number in comparison with the bulk of the work of the laboratory, which embraces not only the whole field of physics, but electricity, metallurgical chemistry, and aerodynamics. A number of problems in connexion with refrigeration are being investigated by the Food Research Board. A novel apparatus has been constructed at the laboratory for controlling humidity conditions in food and other forms of storage. Nearly 700,000 clinical thermometers have been tested during the year, and it is remarked that the quality is well maintained, and that the proportion of instruments which fail to obtain approval and marking is now low. Clinical thermometers made of soft soda glass are more likely to develop defects due to the presence of air than are instruments constructed of lead or other accepted thermometric glass. Some useful work has been done in optics, particularly in colour standardization; here a suitable filter for producing a standard of white light has been evolved, and now requires only some modification in detail. Among other lighting inquiries in progress is an investigation of the characteristics of light transmission of the commercial types of window glass. Experiments, relating in the first instance to compositors, have also been carried out, in association with the Industrial Fatigue Research Board of the Medical Research Council, on the effect of illumination on accuracy and speed of work, but here again the work is at a stage at which apparently not even a provisional report can be made. All this is the most cursory glance at the activities of a great institution, with a staff of 500, engaged continuously upon a bewildering multitude of subjects, including, to take examples at haphazard, the wind resistance

<sup>1</sup> The National Physical Laboratory: Report for the Year 1924. H.M. Stationery Office, Adastral House, Kingsway, W.C. 8s. 6d. net.

of motor cars, the expansion of concrete, the properties of lenses, the thrust of propellers, the measurement of carbon dioxide, and the problems of sound. On this last subject a number of large- and small-scale tests of the absorbing and reflecting power of materials have been made, and the advice of the laboratory has been sought by various bodies—including the Ulster Government, for its Parliament House—on the acoustics of buildings.

#### TYPHOID FEVER IN A LONDON BOROUGH.

LATELY (March 21st, p. 563) we gave some account of an outbreak of milk-borne enteric fever in a rural district in Lancashire, and in that connexion made some observations on public health administration in rural districts. There has now come to hand a report by Dr. Geoffrey E. Oates, M.O.H. Bethnal Green, of a similar outbreak in that borough. It was tackled promptly, all modern means of investigation being brought into immediate use, yet the disease, which came under notice at the end of September, 1924, was not extirpated until the end of the year. The number of known cases was 81, and all were typhoid fever, not paratyphoid. The deaths numbered 12, or 14.8 per cent. As in the Lancashire outbreak, the spread of the infection was largely due to milk. Of 65 primary cases, 51 had milk from one dairy, and a few of the other 14 may have consumed the same milk on occasion. The first notification was on September 27th, but the milk supply of that case was not from the source implicated in the outbreak as a whole. Within a few days three more cases were intimated, all among customers of one milk dealer, and it was found that the proprietor and manager of the business was in bed on the premises, suffering from what had been regarded as an influenzal illness. The possibility of typhoid was discussed with the medical attendant, but ruled out for the time being. In two days, however, the patient was removed to the London Hospital, and there the diagnosis of typhoid fever was made. This illness had begun in the middle of September, and from the start no part was taken by the patient in the conduct of the business, though he took to bed only on September 23rd. When the early notifications were made, every one of thirteen persons resident or employed on the premises was examined by the usual tests, but without practical result. The thirteen included three roundsmen, one of whom, owing to the result of an agglutination test, came under suspicion, but examination of excreta proved negative, and, in fact, the rounds of all the three men were affected to the same extent. A veterinary examination of every one of forty-five cows also proved negative. The dairy premises, though they had no pasteurizing plant, could not be blamed for the outbreak. In spite of careful exploration of all avenues of infection that could be thought of, the ascertained facts were so puzzling as to prevent Dr. Oates from arriving at a very definite conclusion, and he submits two or three different hypotheses. Against the suggestion that the proprietor and manager might himself have been the origin of the outbreak are the facts that the source of his own infection was undiscovered, and that by the time he began to feel ill four cases had already occurred among his customers, and six others had been infected. Indeed, if he were responsible he must have been a carrier of the disease three weeks before he sickened, and also, Dr. Oates points out, he must have infected the last primary case, though that case sickened on November 12th, nearly seven weeks after the proprietor himself went to bed ill. Further, it has already been stated that the proprietor was taken to hospital early in October, so that some of the primary cases must have had a remarkably long period, if not of incubation, at least of non-infection. Another hypothesis considered is early and temporary pollution of the milk

supply, which might have infected alike the proprietor and some of his customers, but there is no evidence of this. A further possibility is a continuous undiscovered source of infection all through September and October, but to Dr. Oates and those whom he consulted this seemed impossible. So firmly was this view held that Dr. Oates states that he took the responsibility for advising the borough council not to interdict the milk supply. Shellfish, greenstuff, ice cream, and fried fish were all considered, and ruled out. In the course of his summary and conclusions Dr. Oates states that the dairy proprietor "was probably the source of infection, but whether he contracted typhoid fever from his own milk supply in common with his customers or from another source is uncertain." Other points are that there was striking evidence that the nursing of typhoid by unskilled persons is dangerous; that during a typhoid epidemic all cases of continued fever should be notified and removed to hospital for diagnosis; that bacteriology contributed to the control of the outbreak; that early notice should be given of any illness in a dairy business; and that there should be systematic medical inspection of milk employees.

#### THE PHARMACEUTICAL CURRICULUM.

PHARMACISTS have now to bear a heavier load of responsibility than was previously the case, and consequently it has been felt for some time that changes in the education of pharmaceutical students, and in their qualifying examinations, have become necessary. New regulations introducing modifications into the three examinations (primary, preliminary scientific, and final) have now been approved by the Council of the Pharmaceutical Society of Great Britain. The new requirements for the preliminary examination prior to registration as a student provide for one language other than English to be offered, so that Welsh is now admitted. Latin is, however, not a compulsory subject, although in the final examination the student is tested in the translating of Latin prescriptions. Before entering for the second examination the student must be certified as having received an approved systematic course of instruction in chemistry of at least 200 hours, and in botany and in physics of 120 hours each. Before entering for the final examination, which enables the candidate to use the title "pharmacist" and to engage in the business of a chemist and druggist, the candidate must have received training under the supervision of a pharmacist for 4,000 hours, in accordance with the Pharmacy Acts of 1868 and 1908, including not less than two years in a chemist's shop or hospital dispensary. He must also have received an approved course of instruction of not less than 720 hours in the subjects of the examination, which include pharmaceutical chemistry, pharmacognosy, pharmacy, and forensic pharmacy. In addition to this qualifying examination for registration there exist also examinations for the title of pharmaceutical chemist, and for the new degree of Bachelor of Pharmacy, conferred by the University of London. Registration as an "apprentice" or "student" will still be possible under the old regulations until January 1st, 1927. The date up to which a candidate who has passed Part I of the qualifying examination will be exempted from the new curriculum of Part II has been extended to August 1st, 1928, so that students will be able to prepare for both parts of the examination on a nine months' course up to and including the course which begins in October, 1927. Moreover, until August, 1928, candidates may continue to enter for both parts of the examination at the same time, but they may not proceed to the qualifying examination until they have received a certificate of having passed the preliminary scientific examination. These extensions largely do away with the injustice that would have followed an earlier enforcement of the new

regulations; and, further, the President of Council of the Pharmaceutical Society has expressed the hope that it may be possible to introduce amendments of the Charter, and, if necessary, of the Pharmacy Acts, in order to obtain a more representative governing organization in place of the present consultative and advisory body.

#### THE CAMPAIGN AGAINST CANCER.

THE quarterly meeting of the Grand Council of the British Empire Cancer Campaign was held on April 7th, with the Lord Chancellor, Viscount Cave, in the chair. Sums amounting to nearly £12,000 in all were allocated, for the purpose of research in cancer, to the following institutions and individual workers: £3,000 to the Middlesex Hospital; £2,500 to the research department of the Cancer Hospital; £1,695 to St. Bartholomew's Hospital, for radiological research; £400 to St. Mark's Hospital; £500 to Dr. Thomas Lumsden of the Lister Institute; and £300 to Dr. Malcolm Donaldson of St. Bartholomew's Hospital to facilitate research into certain forms of inoperable cancer. A further sum of £1,400 was granted to the Middlesex Hospital for special radiological research, subject to confirmation by the Radiology Committee of the Medical Research Council. The above sums are in addition to grants in furtherance of cancer research, amounting to £6,480, made during the current financial year; nor do they include the sum of £5,000 for radium, for use in the cancer research departments of St. Bartholomew's Hospital and St. Peter's Hospital, by the cancer research committee of the London Association of the Medical Women's Federation, and in the radium emanation depot to be set up at the Middlesex Hospital. The foundation of a periodical to contain abstracts on cancer research throughout the world, and the formation of a library of reprints, was the subject of a report from the Scientific Advisory Committee. A sub-committee to work out the details was appointed as follows: Sir William Leishman, Director-General A.M.S.; Professor C. J. Martin, director of the Lister Institute of Preventive Medicine; Dr. Archibald Leitch, director of the Research Department, Cancer Hospital, London; and Professor W. S. Lazarus-Barlow, of the Cancer Research Laboratory, Middlesex Hospital. It was reported that the questionnaire on cancer has now been circulated, through the agency of medical missionaries, to some 900 centres in different parts of the world.

#### THE EQUIPMENT OF THE PRIVATE RADIOLOGIST.

Two years ago Dr. A. E. Barclay, now the president of the Röntgen Society, gave a description before that body of the organization and equipment of the x-ray department of a large hospital (BRITISH MEDICAL JOURNAL, January 13th, 1923, p. 73). As a corollary to this Dr. R. Craig Rodgers of Burnley, in a paper read to the same society on April 7th, described the organization and equipment of x-ray rooms arranged for the private radiologist. He had in mind the radiologist who found it necessary to undertake all forms of diagnosis and treatment, and to utilize diathermy, ionization, and ultra-violet radiation. He excluded intensive or deep therapy, believing that this form of treatment would be undertaken in the future only in nursing homes or hospitals where the radiologist could secure the collaboration of physician, surgeon, and pathologist, and an adequate nursing service. The primary requirement for the x-ray department was a house in a central area, but remote from noisy traffic. He found such a house in Burnley, and fitted it up entirely for x-ray and associated work. The x-ray room (two rooms made into one) was on the ground floor; the entrance to it was so arranged that a stretcher case could be carried in from the ambulance and placed on the couch without turning a corner. Such a room, Dr. Rodgers considered, should be bright and airy,

and about twice as long as it was broad; this allowed the essential pieces of apparatus to be placed conveniently, and avoided the interlacing and possible entanglement of overhead gear. The accessory rooms grouped around the x-ray room were the waiting room, two dressing rooms, lavatory, power room, loading room (where cassettes could be loaded and films obtained at a moment's notice), and the photographic room. For the x-ray room panelled walls, although expensive initially, presented many advantages and were preferable in appearance to wallpaper and paint. The illumination of the room was worthy of attention. By using concealed strip lamps in the cornice at the top of the panelling the light was reflected from the ceiling, resulting in an even, diffused, glowing effect, not only restful to the eyes of the operator, but also useful in making them ready for screening. He found it advantageous to place a resistance in the circuit so that the white light could be dimmed out and a violet light started up, which in its turn was dimmed out, thereby avoiding the sudden plunge into total darkness which was distressing for nervous patients. The decoration of the waiting and other rooms was important also. The colour scheme in his own waiting room was a cheerful blue and orange, and as soon as patients entered the house they got an effect of sunniness and cheerfulness even on a dreary day. For the developing room he used a cellar, approached by a winding staircase which served as a light trap. The rooms for diathermy, ionization, and ultra-violet radiation, with a room used as a personal study, were on the upper floor. The power unit, which consisted of a high-tension transformer and a coil outfit, was assembled in a room leading out of the x-ray room, and had a floor of thick concrete, thereby greatly diminishing any vibration from the machinery. This disposal of the power unit in a separate room had many advantages, among them the absence of the usual cabinets, which took up floor space, the greater ease in getting round the apparatus for testing and cleaning, the diminution of noise and vibration, the concealment of any visible sparking, and the elimination of noxious fumes. The principal items of apparatus in the x-ray room were an upright screen stand, a screening couch, a table for the Potter-Bucky diaphragm, a movable tube stand, and switch controls for the transformer and coil outfits. It was desirable to have a ready means of cutting off the electrical supply from the whole establishment, both in order to check expenditure and to comply with the requirements of the insurance companies; therefore he had a main switch placed behind the front door, and made it a rule for the last person leaving the rooms to switch off the current. Dr. Rodgers showed various photographs and plans of this house, and specially emphasized the arrangements for securing adequate ventilation. The poor health of many x-ray workers might be caused, he thought, not only by x-rays leaking from insufficiently protected apparatus, but from unhealthy atmospheric conditions created during the production of the radiations, owing to ionization of the atmosphere, noxious chemical fumes, the by-products produced by electrical discharges, escape of coal gas from interrupters, and also, of course, the products of respiration. The danger arising from alterations in atmospheric conditions in small, badly ventilated x-ray rooms was worthy of greater consideration than it had so far received.

#### THE ADVANTAGES OF DRAFTS.

SIR WILLIAM OSLER said that no author ought to send anything to be printed until he had had five drafts and corrected each. This was the number Renan required. Sir Clifford Allbutt put the minimum at three, not counting the first rough note. Anatole Franco, about whose habits a stream of little books has been appearing since his death, said seven, with an eighth to make sure that the correc-

ons on the seventh had been understood. In the first he alivened what had been platitudinous. The second was for weeding out the dandelions," whos, whichs, and whoms. a the third he eliminated the semicolons, shortened his sentences, and struck out phrases which merely linked one outeuce with another, or marked a transition from one thought to another, a task that should be left to the reader. n the fourth draft he gave special attention to the order f sentences and to the repetition of the same word; he ooked on the recurrence as a warning to rowrite the sentence, not to search for a synonym. The fifth draft saw ho disappearance of adjectives, for he was of the opinion f Voltaire, that though the adjective might agree with the substantive in gender, number, and case, vory often it did ot suit it. From the sixth draft he chipped away what o called the pastry, all that was adventitious and redund- ant, and over the seventh draft ho passed the plane, for, o said, a good writer is liko a good cabinet maker—he planes his phrases smooth. Franco would have agreed with Byron's epigram had ho known it—"Easy writing's d—d hard reading."

#### CONVENTION OF ENGLISH-SPEAKING OPHTHALMO-LOGICAL SOCIETIES.

THE Ophthalmological Society of the United Kingdom, together with its affiliated societies, will, as wo announced ome months ago, hold in London from July 14th to 17th next a Convention of English-speaking Ophthalmological Societies and Associations. Letters have been sent to the presidents of such bodies in the different parts of the British Empire and the United States of America inviting them to appoint official delegates. On the evening before the Convention opens a reception will be held at the Royal Collogo of Surgeons of England. Four mornings, two afternoons, and one evening will be devoted to scientific work. On the evening of July 15th there will be a symposium on the evolution of binocular vision, in which Sir Charles Shorrington, O.M., G.B.E., P.R.S., Sir Arthur Keith, F.R.S., Sir Frederick Mott, F.R.S., Professor G. Elliot Smith, F.R.S., and Professor S. E. Whitnall will take part. The Bowman Lecture will be delivered by Sir John Parsons, F.R.S., on the afternoon of July 16th. One of the subjects for discussion is the microscopy of the living eye. It will be opened by Dr. Gordon Byers (Montreal), Dr. Arthur J. Bedell (Albany, U.S.A.), Mr. Harrison Butler, and Mr. Basil Graves. One afternoon will be set apart for a visit to institutions of ophthalmic interest, and there will be a museum of drawings, instruments, and pathological and anatomical specimens. At a general meeting of the Convention the re-establishment of international ophthalmological congresses on the pre-war basis will be considered. Social functions will include a reception at the Royal Institution by its president and council, a garden party given by Sir William and Lady Lister, and a reception at the Wellcome Historical Medical Museum by the President of the Convention, Mr. E. Treacher Collins. The official banquet of the Convention will be held on the evening of July 17th. On the following day there will be excursions to Oxford and Cambridge, and local committees in various parts of Great Britain will assist those desirous of making more extended excursions. The general secretary is Mr. C. B. Goulden, 79, Portland Place, W.1.

THE Société de Neurologie de Paris intends to celebrate its own twenty-fifth anniversary and the centenary of Charcot by a meeting in Paris on May 25th, 26th, 27th, and 28th. The centenary will be specially celebrated on Tuesday, May 26th, when a series of addresses will be given by representatives of various societies. On Wednesday, May 27th, the Société will hold a discussion on migraine.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

**Divorce and Venereal Disease.**—When the report stage of the Summary Jurisdiction Bill was taken in the House of Commons, on April 8th, Mr. Harney moved to add to the grounds for judicial separation "that her husband is suffering from venereal disease and insists on cohabiting." The cruelty to future generations had, he said, to be remembered, and not only the question of infecting the wife, though that had been held to constitute cruelty. Mr. G. Locker-Lampson replied that the Home Office was advised that the Act of 1895 covered the case, and that no further reference in the present bill was necessary. If in the opinion of eminent lawyers in the House of Lords this was not so, the Government would see that a provision was put into the bill. The amendment was withdrawn.

**Royal Army Medical Corps.**—Sir Philip Richardson asked, on April 7th, whether the falling off in the number of entrants for the Royal Army Medical Corps was not due to the fact that the pay and pensions of medical officers, particularly those in India, were smaller in purchasing power than in 1914. The Secretary for War replied that the falling off was due to a number of causes, and he hoped it would be possible to find a remedy without undue delay.

**Vaccination.**—Mr. Whiteley asked the Minister of Health, on April 7th, what was the criterion of successful vaccination adopted in the classification of small-pox cases by the medical officers of the Ministry. Sir Kingsley Wood replied that the statements of the medical officers of the hospitals to which the cases were admitted were classified as to the presence or absence of vaccination cicatrices. A table supplied by the Minister of Health to Mr. Groves on April 9th shows that in 1872 vaccinations in England and Wales were 85 per cent. of births and the small-pox deaths numbered 19,022, or 8.2 of the population. In 1922 vaccinations were 40.3 per cent. and small-pox deaths were 27. The percentage of vaccination was in 1923 and 1924 not available; the deaths were 7 and 13. In London, in 1872, the vaccinations were 81.9 per cent. of births and the small-pox deaths 1,786, or 5.4 per 10,000. In 1922 vaccinations in London were 45.7 of births and the small-pox deaths numbered 20. In 1923 London reported one death and in 1924 none.

**Conveyance of Tuberculous Patients.**—Sir Kingsley Wood stated, in answer to Dr. Watts on April 7th, that the Minister of Health had been in communication with the Manchester Corporation about the conveyance of tuberculous patients to and from the Baguley Sanatorium in corporation motor omnibuses. Arrangements had now been made for disinfecting such omnibuses after such use.

**Pensions.**—The Minister of Pensions informed Sir Wilfrid Sugden, on April 9th, that the Regional Director of the North-Western Pensions Region, the Commissioner of Medical Services, the Regional Awarding Officer, and the Medical Assessors all denied absolutely the charge that assessors in the North-Western Region were required to reduce a certain number of pensions weekly. Such a practice, Major Tryon added, would be entirely contrary to all instructions. In reply to Sir A. Holbrook, on April 9th, the Minister of Pensions said that the increase in salary of £50 per annum to be given to full-time medical officers of the Ministry was neither a bonus nor a gratuity, but part of a general revision of the remuneration of the administrative medical staff of the Ministry. The work of the Ministry had diminished, but the staff had been reduced correspondingly, and the work and responsibilities of individual officers remained as great as before.

#### Answers in Brief.

At the Chemical Warfare Research Department since 1918 317 officers and 207 other ranks have been subjected to poison gas tests.

The provisional figures for the manufacture of dangerous drugs in Great Britain during 1924 are: morphine 99,400 oz., heroin 16,700 oz., codeine 153,300 oz.

Approximately 100 local authorities in England and Wales possess public abattoirs.

Provision for maternity and child welfare has now been made in every sanitary district of England and Wales. Milk is provided for mothers and young children by 426 local authorities.

The Minister of Labour does not think that the time is opportune to approach the French and German Governments with a view to ratifying the Washington Hours of Labour Convention.

The Home Secretary does not see his way to introduce legislation to allow the children of women prisoners to be born outside of prison; 19 children were born in prison during 1924.

An annual grant of money, varying from year to year, is made to the National Council for Combating Venereal Diseases, and a return is made to the Ministry of Health showing in detail how it is expended. For the last financial year the grant was £9,183.

Expenditure by the State on health, including health insurance, and housing rose from 2s. 3½d. a head of the population of the United Kingdom in 1913-14 to 9s. 1½d. a head in Great Britain in 1923-24.

Of 49,245 recruits rejected by the army as physically unfit in 1924, 12,813 came from London, 3,641 from Glasgow, 2,147 from Gloucestershire, 1,757 from the West Riding, 1,698 from Sheffield, 1,321 from Manchester, 1,283 from Liverpool, 1,090 from South Wales, 1,408 from Birmingham, and 1,075 from Staffordshire.

The completed results of the second quinquennial valuation under the National Health Insurance Act will not be known until after the end of this year.

## THE LONGEVITY OF PHYSICIANS.

## ON THE AVERAGE LONGEVITY OF PHYSICIANS.

BY  
A. B. HILL, B.Sc.

(National Institute of Medical Research, London.)

IMPERFECT as are our means of assessing the hygienic conditions of England and Wales before the establishment of the General Register Office, the work of various vital statisticians, of Rickman and Farr in the past and of Brownlee and others in our own time, has made it almost certain that the general expectation of life in the eighteenth and earlier centuries was less than now; we are well assured that it is still improving.

It is a matter of some interest to try to determine whether what is true for the whole population is true for some particular class of it. Dr. Brownlee, in some unpublished researches to which he has kindly allowed me access, has studied the vital statistics of one part of the medical profession—namely, physicians—might profitably be made. To this end I have utilized the rich statistical material contained in the *Roll of the Royal College of Physicians of London* compiled by Munk, whose record tends back to the foundation of the College in 1518. Down to the beginning of the seventeenth century for statistical purposes and the particulars insufficient for statistical study. Thereafter the material is more satisfactory, and I have carried out the necessary statistical analysis in order to determine the average length of life of a physician at different dates.

The procedure has been to calculate for each individual the record of whom is sufficiently detailed (1) his age at admission as licentiate, candidate, or Fellow, and (2) his age at death. From these data the numbers exposed to risk and the numbers dying at any age have been computed, and the "mean expectation of life at age  $x$ " obtained. The results are shown in Table I. Before turning to this, attention must be paid to two points of importance. (1) The bulk of the records of birth, death, and entry are given in two forms, examples of which are as follows: (a) born 1760, entered 1787, died 1833; (b) entered 1787, died 1833, aged 73. In the building up of a life table these two entries should be treated differently, for in the first case the mean age of entry is 27 years and the mean age at death is 73 years; in the second case the corresponding mean ages are 27½ and 73½ years.\* Unfortunately in taking out the records this point was overlooked and the two classes were treated alike. It was calculated, however, that if all the records were first treated as belonging to class (a) and then all treated as belonging to class (b)—that is, the extreme case—the difference made in the expectation of life at any age is never greater than half a year. The error introduced is thus not of any great importance. Actually treating all the data as class (a) gives the lower "expectation," and to avoid any exaggeration of length of life this was adopted. (It makes some proportion become exposed to risk half a year too early and die half a year too early.) (2) A more important question is the possibility of a bias being present tending to lengthen the expectation of life. This consists of the fact that those members whose records are most detailed may tend to be the more renowned, and hence to some extent the longer lived. There were no very definite signs of such bias to be seen in taking out the actual records, but the possibility must not be overlooked. In Table I, it will be seen, the members have been divided into four groups according to their date of birth. The periods are, roughly, (1) the seventeenth century, (2) the first half of the eighteenth century, (3) the second half of the eighteenth century, and (4) the first quarter of the nineteenth century. No births occurring after 1825 can be used, for this would not ensure the death of all exposed to risk.

\* For in the first case the physician might have died at any age between 72 years (that is, if he were born at the very end of 1760, and died at the very beginning of 1833) and 74 years (that is, if he were born at the very beginning of 1760, and died at the very end of 1833). This gives a mean age at death of 73 years. In the second case the physician died between 73 and 74 years of age—a mean age at death of 73½ years. The same reasoning applies to age at entry.

TABLE I.

The expectation of life at different ages of physicians grouped according to their date of birth.

Age.	194 Births 1570-1689. Expectation of life* at each age in years.	176 Births 1690-1749. Expectation of life at each age in years.	307 Births 1750-1799. Expectation of life at each age in years.	125 Births 1800-1825. Expectation of life at each age in years.
35	30.3	32.1	35.3	—
40	27.0	23.9	31.3	—
45	23.2	25.4	27.2	31.9
50	19.1	22.3	23.1	26.9
55	15.5	18.6	19.4	22.0
60	13.5	15.1	16.1	17.5
65	11.3	12.1	13.2	13.7
70	9.1	8.4	11.2	10.5
75	6.7	5.8	8.5	8.4
80	4.9	4.5	6.3	5.9
85	3.6	3.7	3.9	4.2

\* Complete expectation of life.

For the last group (1800-1825) it was possible only to take out the records of Fellows (the earlier groups comprising extra-licentiates, licentiates, and candidates as well). The *Roll* compiled by Munk gives no records of members born later than 1800, so that to obtain the details for this last group recourse had to be made to the annual lists of the College and to the obituary notices in contemporary numbers of the *British Medical Journal* and the *Lancet*. After the Medical Act of 1858 the numbers of members of lower rank became so great that the births and deaths are rarely recorded, while the task of going through the annual lists would have been very heavy. It was, however, possible to carry on the table till 1825, but the expectation of life cannot be calculated for this period before 45 years of age, for the age of entry as a Fellow is naturally more advanced and the numbers exposed to risk before age 45 are very small.

As would be anticipated, the expectation of life has steadily increased between the earliest period (1570-1689) and the last (1800-1825). At ages 45 and 50 the increase is as much as eight to nine years; in other words, whereas the "average" physician of 45 years of age in the seventeenth century might expect to live to be 68 (according to these data), his prototype at the beginning of the nineteenth century might expect to live to be 77. If he were 60 years of age in the nineteenth century he might expect four more years of life than his ancestor in the seventeenth century. The increases shown between one period and that immediately following it are somewhat erratic, more especially in the last four age groups, where several times an actual decrease occurs. This is probably due in part to the smallness of the sample, so that the numbers exposed to risk at these later ages became too reduced to give consistent results.

A comparison of interest can be made between the average duration of life of these physicians, at different dates, and the average duration of life of English peers at the same periods. The data relating to the latter have been worked out by Dr. Brownlee, to whom I am again indebted for permission to use these hitherto unpublished figures. The comparison is set out in Table II.

At each period, it will be seen, the physicians of 35, 40, and 45 years of age had an expectation of one to two years' more life than the peers of corresponding age. At the later ages, in the 1570-1689 period, there is little difference between the two classes until the age of 75 is reached. At and beyond that age the peers hold a distinct superiority. In the period 1690-1749 the physicians continue to have the greater expectation up till 65 years of age. At 70 and beyond the peers have again the superiority. In the last period (the dates are not quite identical for the two classes) the physicians continue to

TABLE II.

Comparison of the expectation of life of physicians and peers\* at different dates.

\* These figures relate only to married peers. The expectation of life for married classes is, however, usually greater than that for the unmarried, so that all peers would possibly be at a still greater disadvantage in comparison with the physicians.

have the larger expectation until the final age of 85 years, when their expectation is 0.3 of a year less than that of the peers.

These variations may again be partly due to the small numbers of physicians exposed to risk at the later ages (the largest group is that of 1750-1799); on the whole, it does appear that the physicians are the better lives, and more especially so at the earlier ages. Perhaps they more easily follow a simple life and more easily pursue "the even tenor of their way" (in spite of a life of harder work); or possibly they constitute a "select" class even in comparison with the peers—to enter at all upon the profession of medicine demands a certain level of health. It is possible, too, that by the age of 35 years, at which age the expectation of life is first calculated, the physician has acquired some immunity to diseases such as tuberculosis. On the other hand, constant contact with all forms of disease would, it might be thought, expose the physician to greater risks than those run by a normal population.

An indication as to whether a more modern population of doctors is a select class in comparison with the whole male population can be gained by use of the occupational death rates, for 1910-12, for physicians, surgeons, and other registered practitioners. From these rates the expectation of life can be calculated for this class by the method devised by Dr. E. C. Snow (Cmd. 1010). A slight adjustment is necessary to obtain the years of life lived over 75. The death rate is given for age group 75 years and over. It is required for 85 years and over. The procedure has been to divide it in the same proportion as the death rates for all English males of 75-85 years and 85 years and over bear to one another. This, if anything, will probably understate the expectation of life for the doctors, but the error can be only very slight, and an alternative method of obtaining their expectation gave very closely similar results.

In Table III comparison is made between the expectation of life for practitioners, thus calculated, and the expectation of life for all English males (1) based upon mortality in 1838-54, and (2) mortality in 1910-12.

It will be seen that the medical class has a longer expectation of life—a year at 35 years of age—than all English males (1910-12 mortality), and thus they are to some extent a select population or exposed to less risks of mortality. The physicians on the Roll of the College at the earlier dates would be a still more select population, for they might be said to represent Harley Street, while the 1910-12 mortality represents rather the general practitioners. Dr. William Guy, from an examination of length of life of members of the medical profession dying between 1848 and 1853, came to the conclusion that "the duration of life is greater among physicians and surgeons than among the

TABLE III.

general practitioners of medicine and surgery"—but his data were scanty (On the Duration of Life among Medical Men, *Journal of the Statistical Society*, vol. xvii, 1854). By referring to the expectation of life of physicians whose births fall between 1690 and 1749 (Table II) it can be seen that they are superior in length of life to their brethren dying in 1910-12 (Table III).

Realizing thus how select is the class in question it is not so surprising to observe that the physicians born in the seventeenth century have a longer expectation at nearly every age after 35 years than all English males dying in the second quarter of the nineteenth century. The peers do not hold a similar advantage (except at the later ages) till the period 1690-1749. On the other hand, the physicians born in this period are superior in length of life to all English males dying in the early years of the present century. Or, if mortality in 1910-12 be roughly translated into births between 1810 and 1875, the expectation of life at ages 35 and over of males born between these dates is inferior to the expectation of this select class of physicians born over one hundred years earlier.

In conclusion, I wish to express my indebtedness to Dr. M. Greenwood, at whose suggestion and with whose kindly advice this paper was undertaken; and likewise to the Royal College of Physicians for the facilities readily placed at my disposal.

## POST-GRADUATE STUDY IN LONDON.

### RESUMED DISCUSSION.

THE discussion on post-graduate education in London, held under the auspices of the Fellowship of Medicine and Post-Graduate Association, which was adjourned on March 18th,<sup>1</sup> was resumed at the house of the Royal Society of Medicine on April 8th. There was again a good attendance.

Sir W. ARBUTHNOT LANE, who presided, said that many helpful suggestions had been made in the first part of the discussion, and these it was hoped to incorporate in the work of the Fellowship. That the Fellowship had met a need was proved by the increasing number of practitioners who took advantage of its facilities.

Sir THOMAS HORDER, in opening the discussion, said that there was general agreement on two points: the need in London of post-graduate education, and the desirability of extending the present efforts of the Fellowship. He shared the view already expressed that the post-graduate habit in this country needed stimulating. The sooner it was cultivated in Great Britain the better. It would be lamentable if the habit had to be forced upon the profession from outside, yet it was within the bounds of possibility that the public or a wiser Government than had yet appeared might

<sup>1</sup> BRITISH MEDICAL JOURNAL, March 28th (p. 613).

POST-GRADUATE

758 APRIL 18, 1925]

make it a necessity. Of the suggestions he himself had to make, two were not new to the Council of the Fellowship, but before whom he had advanced them several times, and both had been received sympathetically. The first was that the panel—if such a term could be used for the 270 medical men whose names were set out as ready to give post-graduate instruction—should be made smaller and yet smaller. It led to confusion, whether or not the members of the staff of various hospitals, assist. The panel of post-graduate students must be kept men—men whose names had been suggested to the list in order to get an suggestion was that an certain teachers in post-

had been recalled to the panel—if such a thing had been possible—men whose names were smaller. It led to confusion of the staff of various hospitals, had expressed willingness to assist. The panel of post-graduate tutors must be keen men—men whose names had not been merely added to the list in order to get an impressive array. His second suggestion was that an attempt should be made to recapture certain teachers in the undergraduate schools. It was a severe blow to the graduate teaching when the deans and committees of the majority of undergraduate schools withdrew their active interest. Such action might have been in the interest of the schools concerned, but so far as post-graduate education was concerned the result had been very unfortunate. He held that the dean of a medical school should not have so much control over the teaching power of members of his staff as he has given adequate service to the teaching post-graduates, he should be without running the risk of giving them the undesirable, but desirable, opportunity to do what they please.

If a man, having given up his own practice, wished to become a teacher of undergraduates, though probably it might be desirable that he should be allowed to do so without running the risk of becoming unpopular, the two classes of students, that in order not to mix the two classes of students, that he should undertake his post-graduate teaching elsewhere than at his own hospital. Sir Thomas Horder added that recently he wrote to seventeen teachers attached to medical schools, asking them whether they desired to help in post-graduate education, and in every case but one—and in that one instance the letter miscarried—the reply was favourable. In the first place, however, the Association had no local habitation or name, and therefore the body of the Fellowship. In the second place, now to live body of the Association to have a local habitation and name, for the Association to have a local habitation and name.

He came now to two subjects of importance before the executive body of the Association. By a local habitation as well as a name. The first meant not merely such hospitality as it enjoyed at the time of the Royal Society of Medicine, but a centre where tuition could go on by demonstration and lecture, something like the Polyclinic of years gone by. This should be known to the hono of post-graduate teaching in London. Secondly, a hostel was almost an essential part of a post-graduate scheme, not necessarily that men from overseas or from other parts of the country should be accommodated at the hostel, but that they should be accommodated at places of conference, and that their stay for post-graduate study should be so arranged that no single be satisfactory for

scheme,

Dr. W. Guérin remarks that facilities for members at the first meeting which had been given at the first meeting of the navy and army, and the lack of any in the civilian medical services. It would plan if the authorities responsible for nation-ance would provide opportunities for tioners to undertake post-graduate study be entirely the gain of the insurance r of the public, and the cost should be b itself, and not by the individual pr men on the panel should at intervals men without pecuniary sacrifice on the where such

men on the leave, without pecuniary centres such as the place where such be acquired as the place where a proper given. He believed that such a proposition forward by the Fellowship of Medicine sympathetic response from Mr. N. he suggested that an influential upon the Minister with this object along these lines by radiologists. Dr. F. HENNING-JONSSON was started, but little progress

secured (in Welbeck Street), and the Institute of Radiology, as it was called, came into being. The Mackenzie Davidson Memorial Fund of some £1,500 was the basis of the venture, but radiologists themselves had raised £1,600 or £1,700, and had guaranteed certain annual funds for some time to come. All this experience seemed to bear out Sir Thomas Horder's plea that a definite home must be obtained before any considerable progress could be made. The Institute of Radiology hoped to take a large share in post-graduate work, and possibly to it might be delegated the work of the Fellowship so far as radiological matters were concerned. Sir J. DUNDAS-GRANT recalled the programme of the old Polyclinic, where the demonstrations, and to some extent the lectures, were arranged on a methodical plan so as to cover various subjects within a certain time. No honorarium was paid, but distinguished lecturers and demonstrators were worthy of adoption. He thought that the Polyclinic was worthy of adoption. The meeting should concentrate on something immediate and practical.

Dr. BERNARD MYERS said that he had asked at least a hundred people from abroad or from the provinces what it was exactly that they wanted in the way of post-graduate facilities. What they wanted was practical work; they wanted to see cases, chiefly common cases, not too many rare cases, though a few of those, and cases which they could themselves examine in detail. They desired also to acquaint themselves with the most recent work that was going forward, and from this point of view they liked their instructors to be authorities on the subject. Post-graduates from abroad—even Americans—stated that they could see better cases in London than in any other part of the world. It would be a distinct advantage to have a centre, preferably in Bloomsbury, but the case of the local practitioner, who did not want to be too far away from the calls of his practice, had also to be considered, and arrangements might be made for him to attend a local hospital, even a cottage hospital. About eighteen months ago he made a suggestion to the British Medical Association that men should be sent down to cottage hospitals to give lectures and practical demonstrations, and virtually to take over the work of the hospital for an afternoon, but the British Medical Association thought the time was not quite ripe.

Sir HENRY SIMSON pointed out that there were four post-graduate hospitals which catered for the needs of the doctors in their neighbourhood—the North-East London, the Great Northern, the West London, and the Hampstead General. The reason for the failure of the Polyclinic was because general practitioners did not want lectures; they wanted to see cases and to do practical work. A lecture once a day to general practitioners would not accomplish very much, because they could get all that they wanted along that line from the medical journals. Some post-graduates coming to London desired to see the work of a certain eminent man, others wanted demonstrations in special subjects. All this could be arranged from a central bureau. Others wanted a three or four weeks' general "rub up." For these the hospitals he had named were available. Others, again, were London practitioners who wanted some facilities for study on just one day a week. The post-graduate hospitals covering four districts of London should go some way to meet this need also.

Professor LOUISE McILROY deplored the absence of obstetrics from the programme of the Fellowship. She knew that a good many graduates coming from abroad were satisfied with the rest of the teaching, but criticized this omission; to make it good would probably necessitate some combination of hospitals and teaching staffs. Ante-natal clinics were being started throughout the country, and young graduates were expected to have a good deal of experience in this direction.

Mr. E. B. TURNER thought that the possibility of a house, including a hostel, as a post-graduate centre in London, in a very favourable situation, was well within the bounds of practical politics. The expenditure would be comparatively small, and the hostel might even be made a remunerative speculation which would assist the general funds. Those who came for post-graduate work wanted, not the set academic lecture, but the cases which they could see and examine for themselves more intimately than cases shown in illustration of a clinical lecture. They wanted initiation into the technique of case management. It would, of course, be a great thing to establish a central post-graduate hospital; in the meantime, why not make use of the wonderful clinical material available in Poor Law hospitals? With regard to the granting of study leave to insurance practitioners, as Dr. Griffith had suggested, the insurance practitioner was in the great majority of cases a private practitioner as well, and although the Ministry of Health might make arrangements for the carrying on of his insurance practice during his study leave, he would still find it difficult to get away from the calls of his private practice.

Mr. J. P. LOCKHART-MUMMERY said that two things were necessary—a keen desire for post-graduate work and a central institution. The main difficulty was the question of money. It was no use to ask the public to give money for post-graduate teaching. Post-graduate work had got to "carry its own load." Could money be got out of

post-graduates? His own belief was that it could not. There were over 40,000 practitioners in this country; if 5,000 of them would pay £1 a year a central institution could be run on most satisfactory lines, but he was not sanguine that the 5,000 would be forthcoming.

Dr. R. A. GRIMMOND also was quite sure that money would not be forthcoming from the public. An appeal might be made to the profession for a moderate subscription which would justify an attempt being made to start a central institution.

Dr. C. M. WILSON said that he did not think the man in general practice would come forward for a fortnight's or three weeks' course. He would come on a particular day or to special lectures whenever the material was provided which he desired. With regard to overseas practitioners, anyone who had been to Berlin would realize certain respects in which post-graduate facilities in London fell short. In Berlin there was one centre—the university—where everything could be found. In London a man had to go first to one part and then to another. It was quite impossible to give practical lectures and demonstrations to such a large number as a hundred. Practitioners would come even to these set lectures when they were well given, but a polyclinic would not solve the practical problem of the man who wanted to examine his case beforehand and then hear it talked upon.

Sir ARTHUR LANE, in closing the meeting, said that he thought the Fellowship could congratulate itself on the result of the discussion. A comparison with Berlin had been made, but there was one advantage in London as against Berlin, or Vienna, or Paris—namely, that the people who came for post-graduate instruction spoke a common language. All the suggestions made during the discussion would be brought before the next meeting of the Council.

In the course of the proceedings a letter addressed to the officers of the Fellowship from an experienced post-graduate overseas was read by one of the honorary secretaries, Dr. A. J. WHITING. After urging some criticisms of what he had found in London, such as that medical schools were widely separated, that some lecturers failed to put in an appearance when announced, and that the gift of imparting knowledge was not always evident in the teachers, he went on to say that he would be willing to pay a fee of 50 guineas for a month's concentrated tuition, or 100 guineas for a ten weeks' course, a week to consist of five and a half days of six or more hours' instruction a day. For such fees he would expect—

- (1) to see selected out-patients and hear the cases discussed by a master in his own subject; this master should be able to outline his own teaching and then give the various forms of diagnoses and treatment by first-rank men in Europe and the United States;
- (2) to visit wards daily and to follow up medical cases and see surgical treatment;
- (3) to find that all possible examinations (pathological and bacteriological) in regard to a case were done and could be seen;
- (4) to see a first-class x-ray department and operator;
- (5) to see demonstrations on the cadaver and models;
- (6) to have constant revision of anatomy and opportunity for private or team study by post-graduates themselves;
- (7) to see operations done in all branches of any specialty.

This correspondent added that he would not expect lectures of any systematic sort, or a collection of cases and an address thereon, nor did he want long-winded dissertations on this or that theory, or an autobiography of the teacher!

## ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

### MENTAL HOSPITALS ASSOCIATION.

THE evidence given by the Mental Hospitals Association before the Royal Commission on Lunacy and Mental Disorder was reported in the *BRITISH MEDICAL JOURNAL* of March 28th (p. 611). We have since received from that association a summary of the evidence submitted beforehand to the members of the Commission, which embodies points not brought out in the verbal examination of the witnesses. It may be explained that such a summary as this, which is customarily submitted by bodies giving evidence, is for the private information of the members of the Commission, and does not form part of the Commission's proceedings (unless the Commission so orders, as it did in the case of the British Medical Association's Memorandum),

and is not distributed to the press. It is merely a document from which members of the Commission put questions to the witnesses, and the answers to the questions are technically the evidence. We note that the summary is entirely in the name of Sir William Hodgson, who is a member of the medical profession, though Alderman Taggart was associated with him in the verbal evidence. Points other than those brought out in the verbal evidence are as follows.

Sir William Hodgson urged that in future all medical superintendents should be required to hold diplomas in mental science. He described some of the recent statements in criticism of asylum administration as not only unjust, but based upon inadequate experience of the character and work of these institutions. He wished the Lunacy Act of 1890 to be amended so as to prevent any patient from being discharged without the consent of the majority of the committee present at the hearing of the case. Any committee which overrode the opinion of the medical officer who saw the patient from day to day and found himself unable to approve of discharge was incurring a grave responsibility. It was wrong to suppose that insufficient care was taken to protect dangerous patients. Sir William Hodgson went on to refer to the growing improvement in nursing efficiency, and to the full justification of the innovation whereby female nurses were introduced into male wards. Provision made in public mental hospitals for private cases should, where possible, be made in a separate building. The strictly private hospital would always be wanted by a limited class of people. With regard to the general inspection of mental hospitals, medical inspectors should be in the majority on any staff, but legally trained minds were also required to decide many points of difficulty. Inspectors should submit their reports to a small body of educated and experienced men of affairs, only half of whom should be doctors. The importance of having representatives of the public and of local authorities on these bodies was stressed. He pleaded for a more equitable adjustment of the cost of maintenance as between local authorities and the State in the shape of increased Government grants.

With regard to after-care, it was necessary, Sir William Hodgson said, to ensure that any grants under this head should not degenerate into "doles"; they must be used to assist individuals to become self-supporting. But nothing substantial could be done unless the imperial exchequer bore its fair share of the burden. He argued that it would be a considerable economy in management if the medical and nursing staff of a mental institution could properly organize the work of looking after low-grade mental defectives. In connexion with research work, he protested against a clause in the recent Mental Treatment Bill which provided that mental hospitals should carry out research work on a scheme approved by the Board of Control. Many of these hospitals had now well equipped laboratories fitted on modern lines for pathological and bacteriological research, and it was putting back the clock to try to limit the liberty of mind which was necessary for invention and discovery. Any suggestions which the Board of Control might make to the laboratory experts or medical staff would be thankfully received, but to attempt to control this work by a central authority was a step in the wrong direction. Sir William Hodgson's memorandum concluded with some remarks on slanders on mental hospitals, and insisted that the complaints which were made as to ill treatment were in the main quite untrue.

## Scotland.

### PROPOSED MATERNITY HOSPITAL AT INVERNESS.

THE Highland Maternity and Child Welfare Union has issued an appeal on behalf of a proposed maternity hospital at Inverness, signed by the Duchess of Sutherland (president of the union), Lady Lovat (vice-president), and Mrs. Merry of Belladrum (chairman and honorary treasurer). The appeal states that a maternity hospital ought to be established in Inverness for the northern counties. It is suggested that it should contain two wards of six beds each and private wards in which paying patients would be received. Such an institution would provide also a training centre for nurses; there is at present no such centre further north than Aberdeen. The only beds for maternity cases available in the town of Inverness, excepting those in the poorhouse, are three beds in the Bowmont Child Welfare Centre. The union considers it would be necessary to collect £10,000, but so far only £700 is in hand.

### THE CRICHTON ROYAL INSTITUTION, DUMFRIES.

In our last issue (p. 712) particulars were given of the memorial presented by the board of direction of the Crichton Royal Institution to the Secretary for Scotland, urging the importance of making suitable statutory provisions to allow of rate-aided persons being received as

voluntary patients in mental hospitals in Scotland. In his annual report for the year 1924 Dr. C. C. Easterbrook has dealt at considerable length with this grievance; 70 per cent. of the private patients admitted during 1924 to the Crichton Royal Institution came of their own accord, whereas all the rate-aided cases were admitted under certificate. There can surely be no two opinions on the value of the voluntary principle in regard to admission to a mental hospital, and we are in entire agreement with Dr. Easterbrook in his praise of it. The admission of mentally affected persons on a voluntary basis allows of their malady being attended to in time where this is possible, and many patients are thus prevented from drifting into a grave state rendering certification necessary and cure improbable. It is surely, then, necessary that the benefits of early voluntary admission should be available to all classes of the community, and that any impediment to their being utilized by that larger part of the community who seek treatment on account of mental illness should be speedily removed. At the same time it must be noted that the statute does not expressly forbid rate-aided persons being admitted as voluntary patients. It is to the existence of the lunacy grant which is paid to the parish councils in the case of certified rate-aided cases only, and to the fact that few parish councils have been able to see their way to forgo the benefit of this grant, that the present position must be traced. The grant for the year ending May 15th, 1923, amounted to £115,703, or about 2s. 9d. a week for each certified patient. The unwisdom of allowing this grant only in the case of certified patients is already manifest, and a few parish councils have had the foresight to put the interests of the patient before those of a false economy; but insult is added to injury when the certified rate-aided patient is still officially referred to as a "pauper lunatic." It is, to say the least, unfortunate that the official terminology is calculated to wound the feelings of the patient and of his family, and so dangerously to postpone his admission to hospital. Dr. Easterbrook refers to the disability of certification and to that of pauperization. The former would be reduced to its proper dimensions if the practice of admitting rate-aided cases as voluntary patients to mental hospitals were made general. The latter disability he would remove by the transfer of the present lunacy obligations of the parish councils to the District Boards of Control, "thereby bringing the administration of mental disease into line with that of infectious diseases, including tuberculosis."

### SCOTTISH HOUSING AND SLUM CLEARANCES.

At the annual general meeting of the Convention of the Royal Burghs of Scotland, held in Edinburgh on April 8th, housing was one of the main topics of discussion. The Lord Provost of Edinburgh (Sir W. L. Sleight) was in the chair. Provost W. B. Inglis of Alyth moved a resolution to the effect that any future legislation ought to provide that any building which, in the opinion of a local authority, had got into such a state of dilapidation or disrepair as to affect injuriously the interests or amenity of a town or neighbourhood, should be held to constitute a nuisance which the town council should be entitled to require the owner to remove or remedy. The motion was approved although it was pointed out that there would be some difficulty in wording a clause in a bill. Bailie Riddell moved that the liability on the rates of local authorities with regard to all schemes of housing and slum clearance should be limited to a fixed amount in the £ on the public health rate, and that local responsibility should be limited to a definite figure, which should not be heavy. In the Addison Act that principle had been recognized, and he suggested 2d. in the £ of rental was a fair and reasonable contribution by the locality. Sir Henry Keith said that the question of slum clearance had changed considerably so far as the burden of local authorities was concerned within the last two years. When Sir George McCrae was in charge of the Scottish Health Department a proposal had been made to give Scotland £30,000 for slum clearance, to be divided amongst local authorities as far as it would go. This was found to be totally inadequate. More recent

the Government had offered 50 per cent. of the cost of slum clearance, which was the position at present. He had grave doubts whether the Government could be induced to give what Countbridge wanted, and he suggested that the matter should be remitted to the Annual Committee; this suggestion was accepted. Sir Henry Keith called attention to the work of this committee on housing, and said that the Wheatley scheme was not being used to any great extent. Local authorities could proceed under the 1923 Chamberlain scheme with a subsidy of £6, or under the Wheatley scheme with a subsidy of £9, but with limitations in regard to rents. Some of the English authorities were continuing under the Chamberlain scheme because it gave a greater flexibility than the Wheatley scheme in regard to charging an economic rent. Housing, he said, continued to be a war problem, and for that reason the State, he thought, should bear the burden of the excess expenditure.

#### PERTH INFIRMARY AND DUNDEE STUDENTS.

The students of University College, Dundee, on April 3rd and 4th carried out an intensive campaign in Perth with the view of clearing off the deficit of £1,289 which had been incurred in the work of Perth County and City Royal Infirmary during the past year. The students arrived in the city on Friday in motor vehicles lent for the occasion, and scattered over the towns and villages surrounding the city, where they spent the greater part of the day in collecting a sum of £250. On the same evening a variety entertainment, held in the Alhambra Theatre, Perth, added another £107. During Saturday the activities of the students, who were clad in many varieties of fancy dress, were directed to collecting in the city of Perth. During the day an amusing interlude took place when the Lord Provost of the City, the Hon. John Dewar, and the general manager of the General Accident Fire and Life Assurance Corporation, Mr. F. Norie-Miller, were "kidnapped" by students disguised as brigands and driven through the streets of the city in a motor lorry to be "sold" by public auction in the local market for a heavy ransom to be devoted to the funds of the hospital. The festivities of the day were ended by a hockey match, procession, and dance, and resulted in a total collection of well over £1,000.

#### NEW TYPE OF HOUSE.

A new type of dwelling-house, designed and constructed by Mr. J. Livingstone, building contractor, Falkirk, was inspected on April 8th by a large deputation from the Corporation of Edinburgh, which was favourably impressed by the house. It is built of concrete slabs in a reinforced frame with a continuous cavity all round the foundation as a protection against damp. The model house inspected consisted of a bedroom, living room, "kitchenette," and bathroom; it had been erected by three men in a week, and could be sold for £275.

## England and Wales.

#### LEEDS INFIRMARY.

A CONSIDERABLE amount of anxiety is felt with regard to the General Infirmary at Leeds, the present financial position being unsatisfactory, while the pressure of general work continues unabated. At the end of 1924 no fewer than 1,347 patients were awaiting admission, and at one time during the year there were as many as 1,530. The number of casualties treated in the hospital has increased, and out-patient attendances mounted from 260,794 in the previous year to 336,462. The ordinary income decreased from £72,012 in 1923 to £69,069, and, though there was a reduction in expenditure, there remains a deficiency of £27,293 on the year's working; in addition to this there is an overdraft at the bank of £50,000. In spite of the severe trade depression Sir Edwin Airey's Fund for Leeds hospitals has already reached over £80,000, and when the

infirmary obtains its share from this fund the financial position will be considerably relieved. The chairman, Mr. T. L. Taylor, at the annual meeting on March 26th, pointed out, however, that it was now necessary to take steps to increase the ordinary income materially. During the last six months serious consideration had been given to the question of requiring some payment from patients, and a special committee had been formed in order to devise some scheme for submission to the hospital board. The Workmen's Hospital Fund had increased considerably during the previous year, owing to extra money received from collieries, and if this advance continued the income would approach the expenditure very closely. The growth of the dental school had been so vigorous that fresh accommodation had become necessary. It had been decided, therefore, to provide a site on which the University would build a new dental school.

#### NOTTINGHAM CHILDREN'S HOSPITAL.

Notwithstanding the shortage of accommodation, particularly in the dental, massage, and electrotherapeutic departments, the work of the Nottingham Children's Hospital increased considerably during 1924. The gift to the hospital of an apparatus for the production of ultra-violet rays has been of very great benefit to the children, and the treatment of various diseases has been very much improved by it. The erection of the new wing of the hospital is continuing steadily, and at the annual meeting of the hospital on April 7th the chairman, Mr. H. Bell Tawse, F.R.C.S., expressed the hope that it would be in full working order by the summer of 1926, in time for the Annual Meeting of the British Medical Association. The annual report showed that there was a surplus of income over expenditure for the year of £479, subscriptions having slightly increased, though donations and box collections were lower. During the year 600 in-patients had been admitted, and 239 operations performed. In the out-patient department 2,082 children had been operated upon under anaesthetics, an increase of 511 over the previous year.

#### FRENCHAY PARK, BRISTOL.

The Bristol public health committee proposes to develop its Frenchay Park estate extensively on Alton lines, and so avoid the necessity of sending patients to distant hospitals. For many years the problem of crippling due to tuberculosis has been under active consideration by the committee, and it is now hoped to concentrate treatment locally at Frenchay Sanatorium. When this has been accomplished there will then only be necessary the provision of a seaside sanatorium to take up the function of Hayling Island in the Alton scheme. This addition will probably have to wait until private benevolence is forthcoming. The appointment of a consulting orthopaedic surgeon has enabled the facilities for treatment in Bristol to be made more complete. At the suggestion of the chairman of the health committee a small subcommittee has been formed to consult with other committees concerned with a view to providing better treatment for cases of crippling not included in the tuberculosis scheme. Children under the age of 5 suffering from paralysis and in need of institutional treatment are dealt with under the infant welfare scheme; but there still remains a considerable number of patients for whom provision cannot be made by health committees, but who come under the care of the education committee, which is at present unable to obtain a grant for capital expenditure, although a grant is available for maintenance. Voluntary help is, therefore, necessary, but the Bristol education committee has been able to provide a clinic for physically defective children to accommodate 140. When necessary these children are conveyed to and from school in special ambulances. An orthopaedic surgeon has been appointed, and a fully equipped treatment centre is provided. It is hoped that by extending the accommodation of Frenchay estate it will be possible to economize expenditure considerably, and yet enable a finer building to be erected for the available money than would be the case if a site had to be found elsewhere.

## Correspondence.

### THE DECLINE OF LITHOLAPAXY.

SIR,—I have read with much interest the article in the *BRITISH MEDICAL JOURNAL* of April 11th (p. 690) by Major-General Hooton, C.I.E., Poona, India, formerly my house-surgeon at the Manchester Royal Infirmary, on the decline of litholapaxy. About six months ago my attention was drawn to this subject, for I found that in the previous ten years (1914-23), while only 6 operations of litholapaxy had been performed in the Manchester Royal Infirmary, the cases of suprapubic lithotomy were 65 in number.

On making inquiries at several of the London hospitals it was ascertained that litholapaxy, which during the war had temporarily fallen into disuse, was again coming into favour. Mr. Hamilton Bailey of the London Hospital informed me that in the ten years ending 1922, 34 cases had been treated by litholapaxy out of a total of 131 cases of vesical calculus. Mr. Geoffrey Keynes of St. Bartholomew's Hospital reports 19 cases of litholapaxy and 33 cases of suprapubic lithotomy during the same period.

In 1881 my first operation was performed for stone in the bladder. In 1910, on retiring from the active staff of the hospital, my last operation was undertaken, having in the interval operated upon 170 cases of calculus vesicae. In 62 cases, or more than one-third, litholapaxy was the operation selected. In the 62 cases of litholapaxy the operation proved fatal in only one case—namely, a male patient who was in his 73rd year.

Litholapaxy is an operation which may safely be performed at any period of life—in the very young as well as in those advanced in years. Six of the patients were between 70 and 80 years of age. Ten were under 10 years of age; in six the age did not exceed 5 years, the youngest being 3½ years of age.

My thanks are due to Mr. Geoffrey Keynes, Mr. Hamilton Bailey, and the surgical registrars at the Royal Infirmary (Messrs. Galloway and Scotson) for the above figures.—I am, etc.,

F. A. SOUTHAM,  
Consulting Surgeon, Manchester Royal  
Infirmary.

April 11th.

### THE SEPARATION OF THE PLACENTA.

SIR,—I was very interested to read Dr. Vaughan's memorandum on the separation of the placenta (*BRITISH MEDICAL JOURNAL*, April 4th, p. 656).

For many years it has been my custom to leave untied the maternal end of the umbilical cord. The chief advantage lies in the better separation of placenta and membranes. It is difficult to say whether it lessens the risk of septic infection through the maternal sinuses.—I am, etc.,

Dublin, April 4th.

BETHEL SOLOMONS.

SIR,—When assistant in a rural district in the North of England nearly fifty years ago, I was much concerned with the large proportion of cases requiring manual removal of the placenta, and I began the practice of single ligature. I was so impressed with the advantages of it that it has been my invariable practice ever since, and it must be quite forty years ago that I explained its advantages to the class in the Rotunda, but it did not catch on. My original idea was that it lessened the bulk of the placenta, which it does, but it also allows it to fold up so that the edge presents, and it occupies less space in expulsion. I quite agree with Dr. Vaughan that it allows the uterus to contract more efficiently, and lessens haemorrhage, but also, if manual expression is necessary, it is much more likely to be successful.—I am, etc.,

Frome, April 5th.

W. G. EVANS.

SIR,—The late Dr. D. Berry Hart taught that the maternal end of the cut umbilical cord should not be tied, except in the case of twins. His recommendation was based on his theory of the method of the separation of the placenta. See his *Guide to Midwifery*.—I am, etc.,

Elthurst, nr. Rotherham, April 6th.

C. J. HILL ATKIN, M.D.

### TREATMENT OF DIABETES BY RAW FRESH GLAND (PANCREAS).

SIR,—I was interested in the observations of Dr. Hollins and of Dr. Young in the *BRITISH MEDICAL JOURNAL* of March 14th (p. 503) and March 28th (p. 632), and decided to repeat their experiment under carefully controlled conditions.

The first case was a severe one of five years' duration—a woman aged 34, who has been treated with insulin for the last two years. For the last twenty-five weeks she has been on a constant intake of 60 g. carbohydrate, 70 g. protein, and 150 g. fat, together with 20 units of insulin, half an hour before breakfast, and 14 units just before tea. Under these conditions her blood-sugar curve has been much the same day after day (see columns 2 and 3 of table). From March 27th to 31st, both inclusive, she ate daily 2 oz. raw pancreas with her lettuce, the diet and dose of insulin remaining constant. The pancreas was obtained through the courtesy of Messrs. The British Drug Houses, Ltd. It was frozen immediately after removal from the body, and kept on ice right up to the time that it was minced by the patient, a few minutes before eating it with her meal.

Had the raw pancreas any influence on the diabetic state the blood-sugar curve on the fifth day (March 31st) would have been at a lower level, and there would probably have been symptoms of hypoglycaemia during the five days she was taking the raw pancreas. It will be seen from the table printed below that the blood-sugar curve was not appreciably affected: there were never any signs of hypoglycaemic reaction.

Hours after Insulin.	Blood Sugar, mg. per 100 c.cm.		
	March 17th, 1925: 20 units Insulin; no Raw Pancreas.	March 24th, 1925: 20 units Insulin; no Raw Pancreas.	March 31st, 1925: 20 units Insulin; 5th day on Raw Pancreas.
0	223	193	229
1	215	203	206
2	295	147	161
3	264	89	105
4	119	94	74
5	116	108	79
6	101	108	82

Note.—Breakfast ½ hour and lunch ¾ hours after the insulin. On March 31st, 1925, 5 grams of the protein of breakfast were taken in the form of 1 oz. of raw fresh pancreas.

A second patient, a little girl aged 4, who has been on a fixed intake of 40 g. carbohydrate, 50 g. protein, and 80 g. fat, with 35 units of insulin daily, was given fresh raw pancreas by her mother, who obtained it from her butcher herself. She arranged with the butcher that the pancreas should be delivered within a few hours of removal from the body. The child ate 6 oz. in a period of fourteen days, the diet and dose of insulin being unaltered. Neither the hyperglycaemia nor the glycosuria was in the least influenced.

It will be seen, then, that I am unable to confirm the opinion of Dr. Hollins and Dr. Young as to the value of raw fresh pancreas. From the many investigations on insulin reported in the literature, I did not expect that raw fresh gland taken by the mouth would act as a supply of insulin to these patients, but there was the possibility that while their clinical observations were correct, the interpretation of the results was a different one. I would ascribe the improvement obtained by Dr. Hollins and Dr. Young in their patients to alterations in the diet, and not to the action of raw fresh pancreas. At any rate, I maintain that it is unwise in diabetes to claim improvement as due to any particular preparation (including insulin) unless the diet be fixed rigidly and the effect of the diet alone be determined over a period of several weeks or months before trying the preparation. My reason for this is the well recognized fact that (quantitative) dieting alone may achieve such astounding results, particularly in diabetes of short duration.

In experimental work, in order to demonstrate the part played by insulin, I should try the effect of diet alone in the first place, and then add insulin to the same fixed diet. In ordinary practice, needless to say, like many other physicians, I often make use of both insulin and quantitative dieting from the very first day of treatment.—I am, etc.,

G. A. HARRISON, M.B., B.Ch.

The Hospital for Sick Children, Great Ormond Street, W.C., April 8th.

#### NODAL FEVER.

SIR,—Dr. Lendon's article on nodal fever (*JOURNAL*, April 4th, p. 651) raises some interesting questions in regard to this disease. I am, as he says, in general agreement with him in regarding erythema nodosum as a specific infective fever, but before that view is generally accepted several points will have to be cleared up.

In England and on the Continent erythema nodosum has a definite seasonal incidence, the largest number of cases occurring in the second quarter of the year. The absence of such seasonal incidence in Australia is probably due to the more equable climate, but it would be interesting to know if measles and scarlet fever in Australia show characteristic curves as they do in this country. Very wisely Dr. Lendon has laid emphasis on two symptoms of the disease—namely, phlyctenulae and subungual haemorrhages—for the diagnostic value of these has not been generally recognized.

Most of the acute fevers have been ascertained to have a definite incubation period, and a fixed time between the initial symptoms and the appearance of the rash. Both these periods are very indefinite in nodal fever, and it is desirable that observers should publish cases in which one or both appear to be clearly defined.

Before accepting Dr. Lendon's view that erythema multiforme and erythema nodosum are but phases of the one specific fever, further evidence must be brought forward. The first point to ascertain would be whether erythema multiforme has the same infectivity, epidemicity, seasonal, age, and sex incidence as nodal fever. I certainly have seen cases in which it was impossible to say whether the condition was erythema nodosum or erythema multiforme. While agreeing that the proportion of tuberculous manifestation preceding nodal fever is not greater than one would expect; considering how widely spread tuberculosis is, yet I should differ from Dr. Lendon when he says that tuberculous sequelae are comparatively rare. I have witnessed such in at least 10 per cent. of my cases.—I am, etc.,

Clifton, April 6th.

J. ODERY SYMES.

#### HEART STRAIN.

SIR,—The letter by Dr. E. S. Miller (*JOURNAL*, March 7th, p. 482), criticizing Dr. Pullar's and Dr. Brockbank's suggestion that the pressure transmitted backwards from the aorta to the left ventricle during diastole would be greater in the case of a small leak than in that of a large, is opportune, and his conclusion appears to me sound. The size of the leak makes no difference on the wall of the ventricle, for the reasons he states. One must not, however, accept his statement, "there is no analogy whatever with the effect of a Bramah press," beyond the purpose for which he applies that statement.

The heart beat throughout can only be fully understood and followed if the principle of the Bramah press be grasped. For instance, suppose that the aortic orifice were 1 inch square in area, and the internal surface of the ventricle 6 square inches in area, at the moment the ventricle contracts: the ventricle would then have to exert a force great enough to produce a pressure equal to the aortic pressure on each of the 6 square inches of its surface. When, by contraction, it had reduced its internal area to 3 square inches it could produce an equal pressure on those 3 square inches, with only half the force it had to exert when pressing on the 6 square inches of blood surface, and so on. Thus the ventricular effort would be ever decreasing as it contracted, though the pressure on the blood might remain the same.

Now I have shown, in many communications to the

BRITISH MEDICAL JOURNAL, that the advantage the ventricle or auricle gains on contracting roughly increases inversely as the cube of the diameter, of which a large part—namely, the square—is due to the Bramah press principle, for the area of the inner surface decreases as the square of the diameter.

In the case of mitral stenosis, probably the chief reason why the heart can maintain its circulation for so many years is that the auricle, when by its contraction it becomes small, can force its residual contents into the ventricle through the narrowed orifice, even though the ventricle enter into contraction before the auricle has finished. The auricle, by starting its contraction first, becomes small; while the ventricle is filling and becoming large. Hence the auricle, being small, would be more than a match for the ventricle, being large, when their contractions overlap, as they appear to do.

Though the mitral orifice is incompetent, there is, as we know, no regurgitation and no systolic murmur. Nothing can explain this, unless we admit that the contracting auricle is capable of resisting any regurgitation, and, indeed, it is theoretically capable of actually driving its blood on through the narrowed orifice into the big contracting ventricle, while their contractions overlap.

It is only when the auricle dilates that a systolic murmur occurs, with regurgitation and cardiac breakdown.—I am, etc.,

Mentone, March 31st.

D. W. SAMWAYS.

#### INFECTIVITY OF SMALL-POX IN THE INCUBATION STAGE.

SIR,—In his letter (*JOURNAL*, March 28th, p. 636) Dr. Thomas states "emphatically that small-pox is not infectious even after the onset of the symptoms before the rash has appeared."

I must state just as emphatically that it is in certain cases, and give the following particulars to prove it.

Some years ago I was asked by one of the leading practitioners in the town to see the body of a young woman, who had died after two days illness. The symptoms were severe headache, vomiting, with subsequent coma and death. He had been in attendance since the onset of the illness, and attributed the death to some form of meningitis. Small-pox was present in the town, but there were no cases within a mile of the house of the patient, and there was no history that she had been in contact with a case of the disease. There was not the slightest evidence of any rash, congestion, or infiltration of the skin which could suggest small-pox. Such a case, according to Dr. Thomas, could not be infectious, yet twelve days later six members of the family were taken ill with symptoms of small-pox, and on the sixteenth day from the death of the woman there were eight persons in the home suffering from well marked and virulent small-pox, and the disease ended fatally in three.

Inquiries into another case of small-pox, which was discovered in another part of the town, elicited the fact that the young woman had visited the house a fortnight previous to the onset of her illness, when there was a concealed case of the disease. The remainder of the family had no connexion with the second house, and it is hardly likely that eight cases would occur simultaneously, unless the infection had actually been an intimate one, due to residing in the same house.

I have seen other cases which indicate that infection does exist before the rash appears, but none so definite as the above.—I am, etc.,

JAMES B. WILKINSON,  
Medical Officer of Health.

Oldham, April 3rd.

#### IMMEDIATE AND REMOTE EFFECTS OF SUNLIGHT ON THE EPIDERMIS.

SIR,—As a worker with artificial sunlight since 1917, I should like to support Dr. Leoard Hill's views by saying that, "with due regard to dosage," I have never seen the slightest evidence to support the theory advanced by Sir Lenthal Cheate.

In two cases of squamous-celled carcinoma of the hands, after excision of the growth, I have dressed the wounds with gauze and paraffin and treated them with short daily exposures of ultra-violet rays. The results in both cases were most satisfactory, healing with good clean tissue taking place in one case in six weeks, and in the other in four weeks. After eighteen months in the first case and two months in the second, there has been no sign of recurrence and the scars appear to be perfectly healthy. The preceding factor in one instance was apparently a wart,

in the other x rays. The growths in both were examined pathologically, and no doubt could be entertained as to diagnosis.

The case Sir Lenthal Cheatele refers to, in the last paragraph of his letter, was, I have reason to believe, a case of keloid. During the war and after I treated several cases of keloid with ultra-violet rays with most gratifying results. They are tedious, slow cases to deal with, but I have no hesitation in saying that good results are obtained from this method, and I have never seen the slightest sign of malignancy in any case. I merely refer to this because I think Sir Lenthal was under a misapprehension when he spoke of "speculative therapeutical procedure."

In conclusion I would like to refer to the condition of my own hands. After approximately 35,000 administrations of ultra-violet rays I think there is distinctly less sign of "biotripsis" than is customary at the age of 52, though I have never safeguarded my skin in any way.—I am, etc.,

London, W.1, April 6th.

EDWARD JAMES DECK.

#### BACTERIAL VACCINES.

SIR,—On behalf of Dr. L. S. P. Davidson, who is at present abroad, may I take the opportunity of replying to the letter by Dr. Myer Coplans in your issue of April 11th (p. 717)?

If Dr. Coplans will refer to the *Edinburgh Medical Journal*, April, 1925, vol. 32, transactions of the Medico-Chirurgical Society of December 3rd, 1924, pp. 70-78, he will obtain striking evidence in further support of Dr. Davidson's contentions regarding the antigenic value of different types of vaccines. This is embodied in a paper by Dr. Davidson on immunity to the pneumococcus (abstracted in the *BRITISH MEDICAL JOURNAL*, December 27th, 1924, p. 1200).

Having followed closely Dr. Davidson's work, and appreciating the difficulties in interpreting results put forward by Dr. Coplans, I think this paper should help to reassure the latter with regard to the claims which he criticizes. In the experiments recorded in this communication the criterion of immunity has been actual protection of animals from multiple lethal doses, and it is of some interest in regard to the significance of antibody reactions that the results should lead to the same conclusions as those arrived at in the previous paper which Dr. Coplans now comments on.—I am, etc.,

T. J. MACKIE,

Professor of Bacteriology, University of Edinburgh.

April 13th.

#### THE MAKING OF SERUM PEPTONE.

SIR,—In my article on this subject, published in the *JOURNAL* of March 7th, I omitted to mention that with the stronger solutions of peptone, the serum peptone may not appear very readily or get detached from the blood clot sufficiently freely to be poured off. To prevent this, as soon as the tube is removed from the incubator I pass a long and very thin bistoury right round between the blood clot and the glass. Next day, the clot will have collapsed, and the upper part of the tube contains a clear fluid, which is readily poured or pipetted off. It may be as well to mention this.—I am, etc.,

London, W.1, April 8th.

A. G. AULD.

#### Obituary.

DR. WILLIAM WATKIN LEIGH, who died suddenly on April 10th, in his 71st year, was educated at Cowbridge School, King's College, London, and Guy's Hospital, obtaining in 1878 the diplomas L.R.C.P. Ed., M.R.C.S. Eng., and L.S.A. Lond. He joined his father, Dr. John Leigh, in practice at Llanfabon, Nelson, and Treharris, and after his father's death in 1885 he continued the practice until 1919, when he retired, his son, Dr. H. V. Leigh, succeeding him. Dr. Watkin Leigh had held the following appointments: medical officer of health for Llanfabon; senior surgeon to the Ocean colliery, Treharris; the Dowlais-Cardiff colliery, Abergynon; Penalta colliery, Gellygaer; certifying factory surgeon to the Nelson district; Poor Law

medical officer and public vaccinator for the Nelson district of the Pontypridd Union, and for the Treharris, Trelewis, Bedlinog, Gellygaer, Bargoed, Ystrad Mynach, and Llanbadach districts of the Merthyr Tydfil union; medical officer to the Board of Education and the Post Office; Treharris, Bedlinog, and Nelson; medical referee for numerous medical insurance companies; and he was member of the honorary medical staff of the Pontypridd Cottage Hospital. He was an ex-president of the South Wales and Monmouthshire Branch of the British Medical Association, and a member of the Cardiff Medical Society. He was also a member of the governing body of the Church of Wales, and he took a great interest in public affairs of all kinds; he was made a justice of the peace for the county of Glamorgan in 1885. He is survived by his wife, two sons, and one daughter.

Dr. E. TENISON COLLINS of Cardiff died on April 8th. He was a native of Staffordshire, and received his education at the Universities of Edinburgh, Birmingham, and Cambridge; he took the diplomas of L.S.A. in 1880 and M.R.C.S. in 1890. After serving as house-surgeon at the Jessop Hospital for Women, Sheffield, and resident obstetric assistant at the Queen's Hospital, Birmingham, he settled in Cardiff, where he became gynaecologist to the Cardiff Infirmary, the Pontypool Hospital, and Cardiff City Mental Hospital, as well as consulting gynaecologist to the Bridgend and Abergavenny Hospitals. Throughout his life he was closely associated with the Volunteer and Territorial movements, and held the rank of Lieutenant-colonel R.A.M.C.T. (ret.). He had received the Territorial Decoration. He commanded the 2nd Welsh Field Ambulance at Gallipoli in 1915, and subsequently was in charge of one of the medical boards at the Cardiff recruiting headquarters. He was an ex-president of the Cardiff Medical Society. He took great interest in all sports, and was one of the founders of the Welsh Golfing Union, of which he was for many years secretary and later president. He had recently undergone an operation, from which he appeared to be making a quick recovery, when a relapse set in and proved fatal.

#### Universities and Colleges.

##### UNIVERSITY OF LONDON.

THE following have been recognized as teachers of the University in the subjects and at the institutions indicated:

*London Hospital Medical College.*—Dr. G. Riddoch (medicine).  
*Maudsley Hospital.*—Teachers of Mental Diseases: Dr. H. Deane (psychiatry), Dr. E. B. Rieu (medical medicine).

Mr. James Sherrin, C.B.E., F.R.C.S., has been reappointed the representative of the Royal College of Surgeons of England on the Senate.

The ceremony of presentation day will be held in the Royal Albert Hall on Wednesday, May 13th, at 3 p.m. The annual service for members of the University will be held at Westminster Abbey at 5.45 p.m., when the Right Rev. L. H. Burrows, D.D., Bishop of Sheffield, will preach, and the graduation dinner will take place at the Drapers' Hall, Throgmorton Street, at 8 p.m. on the same day.

Four lectures on cardiology will be given at University College Hospital Medical School by Dr. John Hay, Professor of Medicine, University of Liverpool, on June 11th, 12th, 13th, and 14th. Dr. B. Brouwer, Professor of Anatomy in the University of Amsterdam, will give a lecture at Charing Cross Hospital Medical School, on a date in May to be announced later, on the projection of the retina in the brain.

Four lectures on physiology will be given by Dr. H. H. Dale, C.B.E., F.R.S., head of the Department of Biochemistry and Pharmacology under the Medical Research Council, at St. Bartholomew's Hospital Medical School, on May 15th, 19th, 22nd, and 29th, at 5 p.m.

A course of lectures on medical hydrology will be given at the central buildings of the University from April 27th to May 2nd. The lectures will be supplemented by demonstrations and clinical lectures at a British spa.

A course of lectures on mental deficiency, supplemented by a course of clinical instruction, will be given at the central buildings of the University from May 18th to 23rd.

A grant of £1,000 from the Dixon Fund for assisting researches will be received by the Academic Registrar on May 15th, from whom further particulars may be obtained.

A Carpenter medal, together with a money prize of the value of £20 in all, will be awarded by the Senate in 1925 for a thesis

of exceptional distinction in statistical, genetic, comparative, or experimental psychology, including the functions of the central nervous system and special senses for which a doctor's degree (other than the Ph.D. degree) has been awarded during the period of three years ending on May 31st, 1925. No award will be made unless a thesis of sufficient merit is presented. Applications must be sent to the Academic Registrar by June 10th, from whom further particulars can be obtained.

Applications for grants from the Thomas Smythe Hughes Medical Research Fund for assisting original medical research must be sent to the Academic Registrar not earlier than May 1st and not later than June 15th, 1925.

April 23rd is the latest date for the receipt of applications for the University chair of biochemistry, tenable at the Middlesex Hospital Medical School; salary, £800 a year.

#### UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—M. Allan, C. W. Andersen, Bessie R. Barr, J. Barr, M. J. Bastible, J. A. Bell, D. M'D. Bell, N. L. Dennie, Ann K. Black, A. D. Boyd, W. Brock, A. R. Brown, D. Brown, H. Brown, Edna W. Bruce, D. H. Campbell, A. Clark, A. F. Clark, J. S. Clark, D. H. Clutterbuck, E. Cochrane, J. M. Cormack, Elizabeth Comland, J. Cray, J. Crawford, G. Cross, J. Cunningham, Janet B. Cunningham, M. Curran, R. A. Currie, Ethel M. Deane, R. C. Deans, M. O. Douglas, G. D. Draper, Lucy M. Dron, W. W. Ferguson, J. W. Fergie, A. J. Finlayson, J. D. Finlayson, J. Flynn, J. C. Forsyth, J. M. Forsyth, M. A. Foulis, C. A. I. Fuge, Elizabeth S. Galbraith, W. D. Gillespie, T. L. Gerden, Tina Gray, R. G. R. Grieve, J. B. Harrower, R. Harver, Ellen M. Hegarty, J. Hill, G. Hutcheson, R. G. Hutcheson, R. S. Hynd, J. A. Imrie, T. Imrie, R. F. Innes, Dora Karwowski, D. H. Kinnmont, N. M. A. Lees, A. Leiper, M. Lurie, T. B. M'Alcer, D. A. P. Macalister, A. MacArthur, I. E. MacArthur, J. C. Macarthur, A. G. M'Callum, D. M'Callum, N. M'Diarmid, P. A. M'Duggall, D. T. M'Gibben, J. MacGowan, E. J. MacIntyre, N. D. Mackinnon, A. MacLachlan, S. H. P. MacLachlan, N. MacL. MacLean, Elizabeth V. MacLeod, H. A. Macmillan, W. M'Allen, A. E. M'Neil, T. S. Moignan, W. Moiklich, Isomay Mitchell, C. M. Morton, J. Munn, A. G. M. Murdoch, D. S. Murray, J. A. Murray, S. D. S. Park, J. Paterson, W. Paterson, J. Peter, Margaret I. Prangnell, L. W. Quoleh, R. Ramsay, H. C. Reid, T. G. Rennie, A. Roberts, G. S. Robertson, H. J. Scott, Gertrude R. S. G. Smith, H. Smith, J. Smith, J. T. Smith, W. H. Smith, W. F. Stalker, R. G. Stark, Neral MacK. Steele, T. J. Steven, W. R. M. Stevens, M. Stewart, J. M. Stebe, T. F. Straug, D. Struthers, J. W. Struthers, W. Tait, Matilda D. Tennent, D. Thomson, J. Thomson, P. D. Thomson, R. N. Walker, Agnes B. T. Varden, J. Warren, A. W. Watt, J. D. Wilson, J. Wilson, G. M. Wyburn, J. Yeung.

\* With distinction in surgery.

#### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

At the monthly meeting of the Royal Faculty of Physicians and Surgeons of Glasgow on April 6th the following were, after examination, admitted Fellows: James Pearson Brown, D.S.O., Arthur Charles Lodge La Frenais, Thomas Murray Newton.

Dr. James Alexander Adams was elected the representative on the General Medical Council for a period of five years.

## Medical News.

THE Minister for Local Government and Public Health of the Irish Free State has appointed a committee to advise him on the question of the future position regarding medical registration. The committee consists of Senator Dr. O'Sullivan, Dr. T. Hennessy, T.D., Professor A. F. Dixon, Sir James Craig, T.D., Mr. Mannsell, Dr. Coffey, and Dr. Magennis.

THE new nurses' home in connexion with the Royal Berkshire Hospital was opened by H.R.H. Princess Mary, Viscountess Lascelles, on April 7th. The home is a building of three stories, and will accommodate ninety nurses. The British Red Cross Society made a grant of £15,000 towards its cost. Princess Mary subsequently visited the Royal Berkshire Hospital and was conducted over the wards, giving special attention to the children's ward, which was endowed as a county memorial to King Edward VII. She also paid a short visit to the Girls' Friendly Society Hostel, which bears her name, and represents part of the gift of Reading to her on the occasion of her marriage.

THE Committee for the Study of Medical Hydrology in England invites all medical practitioners interested in the subject to take part in the course of lectures and demonstrations at the University of London, April 27th to 30th. Lectures will be given by Dr. Thresh on types of water, Mr. Dewey on hydrogeology, Professor Barcroft on the capillary circulation in the skin, Dr. Fortescue Fox on the use of heat in the treatment of disease, Dr. Burt on disorders of digestion, Dr. Coates on arthritis, and Dr. Rupert Collins on neurasthenia; a visit will afterwards be paid to Buxton. Those proposing to be present at the lectures or at Buxton are asked to notify the Honorary Secretary, Hydrology Committee, University of London, South Kensington, S.W.7.

THREE post-graduate lectures have been arranged at the Manchester Babies' Hospital, Burnage Lane, Levenshulme. To-day (Friday, April 17th) Dr. Leonard Parsons (Birmingham) will speak on the role of fats in the production of infantile atrophy. On Friday, May 1st, Dr. George Graham deals with the use of insulin for young children, and on Friday, May 15th, Miss Herzfeld, F.R.C.S., will lecture on hernia in infants. The lectures will be delivered at 8 p.m.

A COURSE of ten lectures on the treatment of functional nerve disease will be given at the Tavistock Clinic for Functional Nerve Cases, 51, Tavistock Square, W.C.1, on Tuesdays at 5 p.m., commencing on May 5th. The fee for the course to medical practitioners is £2 2s. and for medical students £1 1s. A syllabus of the lectures and further particulars can be obtained on application to the Honorary Lecture Secretary at the clinic.

THREE lectures on recent advances in the study of living cells will be given at King's College, London, by Professor Robert Chambers (professor of microscopic anatomy in Cornell University, New York), on April 27th, 28th, and 29th, at 5.30 p.m. Admission is free.

THE annual congress of the Royal Institute of Public Health will be held at Brighton at Whitsuntide under the presidency of the Lord Lieutenant of the county of Sussex (Lord Leconfield). It will be opened on Wednesday, May 27th, when the mayor of Brighton will give a reception; the six sections will begin their discussions on Thursday, May 28th. In the Section of State Medicine and Municipal Hygiene there will be discussions on immunization against diphtheria, on tuberculosis and employment, on obstetrics and public health, and on the control of venereal disease. The Naval, Military, and Air Section will hold discussions on the teaching of hygiene, and on mother and child welfare in the army, on occupational deafness, and on bismuth in the treatment of syphilis. In the Sections of Industrial Hygiene, Tropical Diseases, and Pathology the presidents, who are respectively Sir Max Muspratt, Bt. (Liverpool), Dr. Andrew Balfour, and Professor E. C. C. Baly (Liverpool), will give opening addresses, to be followed in each instance by a number of papers. In the Section of Women and the Public Health discussions will take place on heliotherapy and actinotherapy, on the relation between mental and physical disorders, and on birth control in relation to infant and child welfare. The congress dinner will be held on May 28th, and a number of excursions have been arranged on other days.

THE annual general meeting of the Hunterian Society of London, which had been postponed, will be held on May 11th, at Simpson's Restaurant, Cheapside.

APPLICATIONS for the Dickinson surgery scholarship must be sent to the secretary to the trustees, Manchester Royal Infirmary, by April 30th. The scholarship is of the value of £75, tenable for one year, and is open to students who shall have received at the University and the Manchester Royal Infirmary instruction in pathology, medicine, and surgery necessary for taking the M.B., Ch.B. Manch. degrees.

At the meeting of the Central Midwives Board for England and Wales on April 2nd Sir Francis Champneys, Bt., was re-elected chairman. The following appointments to act as representatives on the Board were announced: County Councils' Association, Mr. Leonard Henry West, O.B.E., LL.D.; Royal College of Surgeons, Dr. W. S. A. Griffith, C.B.E.; Society of Apothecaries, Mr. Charles Sangster, M.R.C.S., L.S.A.; Queen Victoria's Jubilee Institute for Nurses, Mrs. Bruce Richmond.

DR. PHILLIP JAMES, who has resided in Senghenydd for thirty-two years, has been presented by his friends and patients in the district with a public testimonial, consisting of a cheque for £428, in recognition of his great services to the community. Before going to Senghenydd, Dr. James practised at Pontypridd, and was one of the recipients of the bronze medal awarded in 1877 by the British Medical Association for heroic conduct, self-denial, and humanity at a colliery accident at Pontypridd.

DR. CANVY has been nominated professor of oto-rhino-laryngology in the Strasbourg Faculty of Medicine.

DR. WRIGHT MASON, who recently retired from the office of medical officer of health for Hull, has been presented by the head officials of the corporation with a silver salver as a mark of their good will and esteem.

MR. J. D. ROCKEFELLER, jun., has presented £400,000 to the Tokyo Imperial University to assist in the restoration of the University Library, which was destroyed in September, 1923. This will enable the University to enlarge the plan of the library and to perfect its fireproof, sanitary, and other equipment. The University has also received a grant of £130,000 from the Government. The new library will accommodate 1,000 students, as compared with 300 in the last building. A special fireproof stockroom is to be constructed for particularly valuable books.

THE London office of the Italian State Railways and State Tourist Department (12, Waterloo Place, Regent Street, S.W.1) announces that the annual international visit of doctors to Italian health resorts will take place from September 5th to 21st. Among the places to be visited are San Pellegrino, Fonte Bracca, Aequi, Alassio, San Remo, Ospedaletti, Bordighera, Pietra Ligure, Nervi, Rapallo, Santa Margherita, Portofino, Viareggio, Montecatini, Monsummano, Chianciano, Fuggi. The members of the party (limited to 200 in number) will travel by special train in Italy and will be accommodated at first-class hotels. A limited number of places in the tour are reserved for members of the families of participants. Italian doctors, speaking fluent English, accompany the tour and assist in the medical conference held at each centre. The charge for the tour, including cost of travel from Milan to Rome, railway and hotel expenses, will be lire 1,600 (about £15). Members will be granted reduced rate tickets from the Italian frontier to Milan and from Rome back to the frontier.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proof.

ALL communications with reference to advertisements as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager, 429, Strand, London, W.C.2. Attention to this request will avoid delay. Communications with reference to editorial business should be addressed to the Editor, BRITISH MEDICAL JOURNAL, 429, Strand, W.C.2.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication.

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning.

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2530 (Internal Exchange). The telegraphic addresses are:

EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology Westrand, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westrand, London.

MEDICAL SECRETARY, Mediscera Westrand, London.  
The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Facillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### INCOME TAX.

#### Extension of Premises.

"H." bought a new house over a year ago, and, as there was no consulting room accommodation, had to build additional rooms at a cost of £700.

"\*." In our opinion, no portion of the £700 can be claimed as expenditure deductible for the purpose of income tax, Schedule D, Rule 3, applying to Cases I and II, Schedule D, is to the effect that "no sum shall be deducted in respect of . . . any sum expended for repairs of premises . . . beyond the sum usually expended for those purposes according to an average of three years. . . ." The exact meaning of that rule may be open to some doubt, but it is fairly clear that it would exclude by implication expenditure on adding rooms to an existing house. From a practical point of view, too, the £700 was capital outlay—that is, money invested to bring in returns over a future tract of time; "H." spent a certain sum in acquiring suitable premises, and it is immaterial that the total was laid out in two separate sums and not in a single payment for the final result.

## LETTERS, NOTES, ETC.

### IODINE IN WHEAT PRODUCTS.

MR. ALBERT E. PARKES, F.I.C., F.C.S., public analyst to the Metropolitan Borough of Poplar, has examined a number of specimens of wheat products to ascertain the amount of iodine present, with the following results:

Whole flour: Less than 1 per 5,000,000.  
Whole meal: 2.5 parts per 1,000,000 (17,100 gr. per lb.).  
Bran: 3.8 parts per 1,000,000 (27,100 gr. per lb.).  
Draughts: 0.6 part per 1,000,000 (4,500 gr. per lb.).  
Germ: 3 parts per 1,000,000 (25,100 gr. per lb.).  
Results expressed as iodine: Iodine  $\times 1.2$  = sodium iodide.

## GALL STONES.

DR. DOROTHY A. DALY (Fairlight Sanatorium) writes: I have been interested in the correspondence regarding the age at which gall stones may be found. When a student in Trinity College, Dublin, a girl of 11 was brought into one of the Dublin hospitals as an emergency case of appendicitis. On opening the abdomen the trouble was located in the gall bladder, from which two fair-sized stones were removed. I almost think this establishes a record.

## A NEW TUBERCULIN.

WITH reference to Dr. Lundie's paper, "A new tuberculin," in the BRITISH MEDICAL JOURNAL of February 28th (p. 426) Dr. A. W. CRAWFORD (Bolton) has forwarded the following criticism and queries:

(1) Which serum is used, human or bovine? (2) At what stage is it used—whether in the early stage, when bovine infection is predominant, or in the second stage, from 13 to 19, when there is a combination of human and bovine, or in the later stages, when the human only is found? (3) In one patient both were used with great benefit. To which preparation must the benefit be attributed? It is necessary to understand clearly the stage of the disease and the nature of the tuberculin used. (4) Dr. Lundie asks about a solvent for acid-fast substances associated with the bacillus. The coating of the bacillus consists of insoluble salts with animal matter, of which fat is a constituent. They are soluble in a solution of potash; acetic acid, in my opinion, is preferable to hydrochloric acid. (5) Dr. Lundie states that guinea-pigs are more susceptible to tuberculosis than man: which form, human or bovine?—a very important distinction. (6) Wherever tubercle is deposited there is associated with it the growth of fibrous material, which is nature's method of delimitation, and is of epithelial origin, as in cancer. If this encasing substance is sustained, calcification would ensue and tuberculosis receive a check. I should like to suggest to Dr. Lundie that this might be accomplished by the use of a properly selected tuberculin, combined with prepared juices of embryonic tissues. How far this may go to prevent the spreading of tuberculosis I cannot say, but I think it is a step on the way.

We have submitted this letter to Dr. Lundie, who writes:

In reply to Dr. Crawford's very kind criticism, I use the word "tuberculin" in its original sense, which does not include serums. (1) I have used both human and bovine preparations. (2) "Stage" here would be better expressed as "age incidence." I do not think it a useful guide to treatment, but agree that it is most important to understand both the type of infecting organism and the nature of the therapeutic agent. (3) Both preparations appeared to do good. (4) I did not ask, as I am sure about this point. The acid-fast material is mycolic laurate, said to be held in the form of an emulsion in a protein substrate. I believe it is probably chemically united to protein. (5) I stated that man has a much greater natural resistance than guinea-pigs or rabbits. Bovine tuberculosis is always more virulent to these animals than to man, and I think the human type is sometimes so also. I believe that many children become immunized in course of time by a series of . . . bacilli, administered in all good fa . . . ty of guinea-pig cells concerned in the process. Calcium salts penetrate tubercles with remarkable ease, despite their density and non-vascularity, but the impregnation with calcium experimentally has not been proved to have any beneficial value at all. I do not know what benefit embryonic extracts would confer, beyond causing protein shock, which would be better avoided.

## GOATS AND COWS.

DR. S. K. VINES (W. Hythe, Kent) writes: The old-style farmer has long believed that keeping a goat among the cows "prevents miscarriage." This is, interesting in the light of recent contributions in your columns on the resemblance between *B. melitensis* and *B. abortus*. Goats would seem not to be subject to epizootic abortion. I do not know what proportion of them in this country carry, or have immunity from, *B. melitensis*. Probably the goat vaccinates the cow with a dead culture.

## WILLIAM LEVETT.

G. E. W. writes to point out that the last line on Levett by Dr. Johnson should run "His single talent well employed"—not "simple" as printed by inadvertence in our issue of April 11th (p. 705).

## CORRECTION.

IN our reference on April 11th (p. 722) to the fourth International Medical Congress on Industrial Accidents and Diseases at Amsterdam it has been stated that the president of the Congress was Dr. J. H. van Eden of Amsterdam, and that Sir Thomas Oliver, F.R.S., was the British executive committee. The British executive committee is honorary president of the Congress.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 38, 39, 41, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 183.

## Lumleian Lectures

ON

## SOME FORMS OF VOMITING IN INFANCY.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, MARCH-APRIL, 1925.

BY

H. C. CAMERON, M.D.CAMB., F.R.C.P.LOND.,  
PHYSICIAN IN CHARGE OF THE DEPARTMENT OF DISEASES OF CHILDREN,  
GUY'S HOSPITAL.

## LECTURE I.—VOMITING DUE TO OBSTRUCTION FROM DEVELOPMENTAL DEFECT IN THE UPPER ALIMENTARY TRACT.

PERSISTENT vomiting as a symptom of infantile disorders is frequent enough. It is the rule in dyspeptic states of all sorts as well as in infective pyrexial disorders. Yet, just because of the predominance and frequency of this symptom in many of the most common ailments of infancy, it is especially necessary to bear in mind the possibility that the vomiting may be due to other and local causes, to developmental failure high in the intestinal tract, to inco-ordination of the intestinal musculature, or to purely functional disturbance of the gastric movements.

## THE CHARACTER OF VOMITING DUE TO DYSPEPSIA.

I exclude altogether from consideration the vomiting which is symptomatic of most states of dyspepsia in infants, even although that vomiting may be long continued and severe. In infancy the dyspeptic state is almost always associated with some coincident disturbance of the bowels, and the intestinal disturbance is generally more constant than the gastric. In health the infant's bowels are opened with the least possible disturbance, and the faecal material flows quietly from the anus with little apparent effort. In dyspepsia the character of the stools and the manner of defaecation are both altered. When fermentative changes are in excess the stools are acid and irritating, are hurried along the intestinal canal by powerful peristaltic waves and expelled from the anus with great violence, with the audible escape of gas and with the outpouring of much watery secretion from the bowel. Defaecation is then generally a painful process, as is shown by the facial expression of the infant, by the cry and the movements of arms and legs. The irritating quality of the stools may be gauged by the erythema and excoriations produced upon the skin of buttocks, thighs, and heels wherever the restless movements of the child bring it into contact with the dejecta. When, on the other hand, the putrefactive processes are in excess and the acidity of the intestinal contents is unduly diminished the reaction of the stools is alkaline, the fatty acids combine with calcium and magnesium to form soaps, and the stools become hard and scyhalous. For the infant the ejection of such stools is a matter of difficulty. With great straining and much distension of the anus the stool, sometimes streaked with mucus or with blood, is painfully ejected. In a second group of infantile gastro-intestinal disorders the disturbance is due, not, as in dyspepsia, to changes in the reaction and character of the intestinal contents, but is the accompaniment of an infection, catarrhal or even ulcerative, of the mucous membrane of the intestinal wall. In catarrhal and ulcerative enteritis and colitis in infancy the disorder is also constantly manifested by changes in the stools, and especially by the presence of mucus, blood, and pus in considerable quantities, while defaecation is painful and often accompanied by tenesmus.

Both in dyspeptic and in infective diarrhoea vomiting of stomach contents may be severe and persistent, but the vomiting is then associated with characteristic changes in the stools and in the manner of defaecation. In the conditions of habitual and persistent vomiting which I shall consider it is to be noticed, in the first place, that the stools and the manner of defaecation will show none

of the characteristics of dyspeptic or of infective diarrhoea. In all of them vomiting alone is prominent, associated perhaps with a varying degree of constipation or with the passage of such stools as are characteristic of the state of inanition.

## CLASSIFICATION OF THE CASES TO BE CONSIDERED.

Vomiting, then, so far as it forms a part of the picture of dyspepsia, so far as it is to be regarded as a reaction in the interests of the child designed to assist in the removal of irritating and harmful products of digestion, is excluded from consideration. In these lectures I propose to deal only with the cases of persistent vomiting which are dependent upon some disorder in the mechanism of the movements of the stomach and bowel. In some the disturbance is due to the presence of gross defects in the structure of the alimentary tube; in others neuromuscular inco-ordination imposes an obstruction to the passage of the intestinal contents little less yielding; in yet others the explanation is to be found in a variety of purely functional disturbances.

## VOMITING DUE TO OBSTRUCTION FROM DEVELOPMENTAL DEFECT IN THE UPPER ALIMENTARY TRACT (Lecture I).

## (A) Duodenal Obstruction:

- (1) Intrinsic—Duodenal atresia and stenosis.
- (2) Extrinsic—Abnormalities of intestinal rotation and peritoneal fixation, giving rise to volvulus and kinking of the bowel.

- (B) Pyloric Obstruction: Pyloric stenosis of Landerer and Maier
- (C) Oesophageal Obstruction.

## VOMITING DUE TO OBSTRUCTION FROM NEUROMUSCULAR INCO-ORDINATION (Lecture II).

- (A) Pyloric Obstruction: Hypertrophic pyloric stenosis, achalasia of the pyloric sphincter.
- (B) Obstruction at the Ileo-caecal Valve: Generalized intestinal spasm, achalasia of the ileo-caecal sphincter.
- (C) Obstruction at the Anus and in the Rectum: Hirschsprung's disease, achalasia of the ano-rectal sphincter.
- (D) Obstruction at the Cardia: Cardiospasm, achalasia of the cardiac sphincter.

## SOME FORMS OF HABITUAL VOMITING IN INFANCY (Lecture III).

- (A) Vomiting and Acrophagy.
- (B) Vomiting and Nervousness.
- (C) Vomiting and Idiosyncrasy against Cow's Milk.
- (D) Vomiting and Rumination.

## FREQUENCY OF THE CONDITIONS TO BE CONSIDERED.

Although such a condition as congenital occlusion of the bowel could hardly escape recognition so soon as post-mortem examinations came habitually to be practised upon a considerable scale—Oslander in 1797 was probably the first accurately to describe a case—it is only during the last twenty or thirty years that knowledge has slowly accumulated with regard to the majority of the disorders I shall have to consider. The successful application of the method of examination by Roentgen rays and an opaque meal in the case of young children is of comparatively recent date. The constant development of surgical technique to-day enables us successfully to submit the infant and even the newly born to operative procedures which in the past have invariably proved fatal, while in the case of the primarily functional disorders a clearer appreciation of the nature of the disturbance has enabled serviceable treatment to be devised. But, it may be urged, experience has seemed to show that many, if not all, of these conditions are of considerable rarity. Diligent search in the literature may find recorded perhaps one hundred or more examples of duodenal atresia or a similar number of oesophageal atresia—Spriggs in 1912 in his admirable paper quoted 328 examples of intestinal occlusion, of which 92 were in the duodenum. Of this total he himself provided 24 examples previously undescribed. The next year Edington added 7 very completely studied cases occurring within a short time of each other in his own practice. Jewesbury and Page in 1923 reported 4 cases of different varieties of duodenal obstruction in young infants met with in one year in St. Thomas's Hospital. In 1924 Smellie reported 3 cases of intrinsic duodenal obstruction studied by him in hospital practice during the same year. But the impressions derived from a study of the recorded cases are of little value in indicating the actual frequency of such conditions. Before 1900 the number of cases of hypertrophic pyloric stenosis

was insignificant; they were recognized by only a few physicians who had paid attention to the subject. To-day, although very many still escape detection, the great frequency of the disease is apparent, because a knowledge of its existence and symptomatology has become widely spread, and the lives of hundreds of infants may be said to be saved annually by timely operation. Of the frequency of all disorders in the first days of life we are relatively ignorant, partly because of their real obscurity, but partly because of a pessimistic attitude too widely spread towards the diseases of the newborn which tends to leave recovery to the test of time. Only if the child is born in an institution or hurried in the first days of life to a hospital is the diagnosis likely to be made. Braun calculates that in Germany imperforate anus, which is not likely to escape recognition, occurs about once in 17,000 births. Occlusion at a higher level is estimated by Theremin to occur once in from 16,000 to 55,000 infants. The value of these figures and estimates is very slight. It is at least possible that the frequency may be much greater. Complete atresia is more common in the records of *post-mortem* inspections than partial stenosis, but the partial obstruction is clearly the more elusive and the less likely to be differentiated from a state of marasmus or dyspepsia. Similarly, it is frequently found that spastic states of the bowel, of which the hypertrophic stenosis of the pylorus is the most common, are more apt to pass undetected if the obstruction is only intermittent and of slight degree. Such children waste, their immunity to infection falls and their tolerance for food diminishes, until death ultimately occurs from pulmonary disease or from a secondary state of true dyspepsia. With the exception of hypertrophic stenosis of the pylorus and of some of the minor functional disturbances, one can only conclude that the conditions which I shall describe are not common, but that they are less rare than is generally supposed, and that they are beginning to be identified in increasing numbers as attention is directed towards them.

## I.—ORGANIC OBSTRUCTION OF THE UPPER ALIMENTARY TRACT.

### A. DUODENAL OBSTRUCTION.

It is to duodenal obstruction that I shall devote most attention, not only because obstruction in that situation, taking all cases into consideration, is relatively common, but because the diagnosis, supported by a characteristic radiographic appearance, is often not difficult, and because, sometimes at least, we may hope to save life by means of a timely operation following upon early diagnosis. In the past the interest in these conditions has been mainly in their developmental and pathological bearings. In the future it will pass more and more to the bedside.

The cases to be considered fall into two groups, differing widely in etiology and to a considerable extent in symptomatology, in their treatment, and in their prognosis. They must therefore receive separate consideration.

#### *Etiology.*

**1. Intrinsic Duodenal Obstruction: Duodenal Atresia and Stenosis.**—In the alimentary tract, from the oesophagus to the anus, we meet with cases both of atresia and of stenosis which have been the subject of exhaustive pathological studies. Cordes, Spriggs, Kreuter, Kuliga, and Cautley have contributed valuable studies of the literature. In all situations we meet with three varieties of obstruction: (1) by a diaphragm or membrane, perforate or imperforate; (2) by the interposition in the length of the lumen of a fibrous cord-like structure which may or may not contain a narrow lumen; (3) by complete separation of the gut which terminates blindly and begins again after a gap which is completely unbridged.

The embryological studies of Tandler, Kreuter, Forssner, Odematt, and others have done much to make clear the origin of atresia and stenosis of the alimentary tract. These studies take us back to the fifth week of embryonic life—to a time when the bowel is a simple tube stretching from the mouth to the allantois, and showing but little differentiation into its separate parts except for a slight widening of the stomach and some convolution in that part which is to become the small intestine. The coats of the bowel wall are in no way differentiated, and the

central lumen is lined by a layer of primitive rounded endodermal cells. At this stage there sets in a rapid proliferation of the primitive epithelium, which results in the complete obliteration of the temporary lumen. Only some weeks later does a permanent lumen form by the fusion of certain vacuoles or cleft-like spaces which appear in the solid cord of endodermal cells. The epithelium lining this permanent lumen becomes differentiated into that characteristic of the various parts of the intestine, and the submucous and muscular coats of the bowel become distinct. The growth of the mesenchyme and the differentiation into muscular and fibrous coats may begin at a time when the occlusion by primitive epithelium is still present. This process of obliteration of the lumen of the bowel has been shown to occur normally in the oesophagus of the embryos of many animals (Marshall, Balfour), in the oesophagus of the human embryo (Kreuter), and in the duodenum of the human embryo (Tandler). Forssner has attempted to show that exceptionally it may occur in all situations in the bowel. He has argued very convincingly that the ingrowth of the mesenchyme and the persistence of epithelial occlusion will account for the three types of obstruction, representatives of each of which are found from time to time in most, if not in all, of the segments of the intestinal canal which are developed from this primitive tube. If the persistence of the foetal obliteration of the lumen of the primitive gut involves but a minimal length of bowel the diaphragmatic variety is produced, and the mesenchyme may, or may not, penetrate within its folds. In specimens examined microscopically it is found that the diaphragm in some cases consists mainly of a double layer of epithelium placed, as it were, back to back, while in others the epithelial layers are separated by fibrous tissue and muscle. If, on the other hand, the obliteration extends for some distance along the length of the bowel, the mesenchyme grows closely around the mass of embryonic epithelium, which atrophies and disappears, as such tissue tends to do, notably in the case of the vitelline duct, leaving no trace of its presence. If, as the result of changes in further development, the slender cord of fibrous tissue, enclosing perhaps the remnants of muscle and glandular tissue, is sundered, the two parts of the bowel at birth would be completely separated.

In the duodenum, as in the oesophagus and rectum, we are spared the necessity of discussing an extensive literature concerned to prove that atresia and stenosis by a diaphragm or by the interposition of a fibrous cord may be the result of foetal accidents such as volvulus and intussusception, or of foetal diseases such as peritonitis. If we were dealing with occlusions of the intestine at a lower level, where the bowel has a greater mobility, such factors would have to be considered, although even there it is difficult to understand how a volvulus or an intussusception could disappear, leaving no trace of its presence save a diaphragmatic or cord-like occlusion of the bowel, or to believe that the inflammatory changes involved in peritonitis could take place at so early a stage of foetal life. The belief that duodenal atresia and stenosis are due to a primary fault of development is supported by the frequency with which other developmental anomalies are found in association with the duodenal obstruction (11 out of 57 cases, Cordes).

Bland-Sutton has emphasized that the parts of the bowel which are most prone to exhibit developmental defects are those in which the developmental process is particularly complicated, the seat, as he says, of an "embryological event," as, for instance, in the neighbourhood of the vitelline duct or around the bile papilla. In many cases of duodenal atresia it is clear that the obstruction is closely connected with the outgrowth of liver and pancreas from the primitive gut. Not only are many obstructions found in the near neighbourhood of the papilla, but abnormalities of the common bile duct are frequent accompaniments. Thus, Buchanan describes a case in which the bile duct opened upon the upper surface of a perforate diaphragm, the pancreatic duct entering below. Edington figures his histological examination of a similar case in which the diaphragm was traversed by a channel which was lined by columnar epithelium, continuous with the ducts in the pancreatic tissue above and with the

lumen of the bowel below. Smellie describes a case of complete isolation of the stomach and first part of the duodenum which ended blindly. The gall bladder was in the correct position. The cystic and the hepatic ducts, joining to form the common duct, gradually merged into the second part of the duodenum, so that it was not possible to say where the common duct ended and where the duodenum began; presumably it was just below the entrance of the pancreatic duct. Many other cases of a like nature could be quoted. Often abnormality of the bile duct leads to a double outflow, bile entering both below and above the obstruction. In many cases of duodenal obstruction in which the main orifice of the bile duct is found to be above a complete obstruction the intestines have contained bile. Similarly, bile has been vomited when the papilla is situated below a complete obstruction. That bile so vomited may be due to swallowed amniotic fluid containing bile, or that the bile found in the intestine below an obstruction reached that situation at a time antecedent to the development of the obstruction, are possible, if somewhat unlikely, explanations. According to Savariaud, bile does not normally reach the duodenum until the fifth month. The presence of a minute accessory duct is probably often overlooked, and is the explanation of the presence of bile on what would appear to be the wrong side of a complete obstruction. Spriggs, Cordes, and Cockayne have dealt fully with this point of the distribution of bile in congenital duodenal obstruction. In other cases it may be that the condition is in reality one, not of complete atresia, but of stenosis, and that there exists a minute channel which has escaped detection. The difficulty of detecting minute fistular communications after death is considerable. There is a specimen in the St. Bartholomew's Hospital Museum from an infant, aged 9 months, showing a diaphragmatic septum in the duodenum. There is no evidence of an orifice in this diaphragm, though the history of the case and the duration of life seem to prove that some opening must have existed. We may conclude, with Cordes, that since the region of the bile papilla from an early period in the life of the embryo undergoes radical formative changes as the result of which the liver and pancreas develop, epithelial obliteration in the manner described, which may occur in any situation, is peculiarly prone to affect the near neighbourhood of the ampulla of Vater, and to be accompanied by abnormality in the distribution of bile ducts and pancreatic ducts.

**2. Extrinsic Obstruction: Abnormalities of Intestinal Rotation, etc.**—In the duodenum at the duodeno-jejunal flexure we meet with a second group of cases of obstruction, due also to developmental anomalies but of a very different nature. In the state of development characteristic of the human embryo of the fifth week, the three parts of the intestinal canal are clearly marked by their separate blood supply—the fore-gut digestive in function, the mid-gut absorptive, the hind-gut excretory. The blood supply of the mid-gut is the superior mesenteric artery, which crosses directly to the umbilicus and vitelline duct. A considerable part of the mid-gut lies outside the abdomen, traversing the ring which is to be the site of the future umbilicus. The pre-arterial segment of the mid-gut elongates at a very much greater rate than the post-arterial, which contains the caecum. By the tenth week the coils of intestine come more and more to occupy the abdominal cavity and to leave the umbilical sac. The pre-arterial coils enter first and pass over to the left side of the abdomen behind the transversus colon and behind the mesenteric vessels, so that they come to lie, not on the right, but on the left side of the mesentery. The superior mesenteric artery crosses the pre-arterial gut at a point near the termination of the duodenum, and the primitive relation of this vessel, lying as it does between the duodenum and the colon, is never lost. When later the caecum and ascending colon leave the sac they occupy a situation on the right side of the mesentery, while the descending colon maintains its primitive position on the left.

Dorangements of this intestinal rotation—non-rotation with a left-sided caecum and appendix, reversed rotation with the duodenal loop crossing in front of the artery, and with the colon most posterior of all, malrotation with reversed rotation of the pre-arterial segment, and arrested

rotation of the post-arterial segment—are met with from time to time. The abnormal disposition of the intestine implies abnormal attachments and fixation of the peritoneal folds, and this may or may not give rise to untoward results. Undue fixation may cause kinking of the bowel, especially at the duodeno-jejunal flexure, or there may be direct pressure upon the duodenum by the superior mesenteric artery or by abnormal peritoneal folds. On the other hand, undue want of fixation predisposes to volvulus. Dott, in a very valuable paper, has pointed out how widely this characteristic volvulus neonatorum differs from the usual variety of acquired volvulus. Acquired volvulus is confined to a limited portion of gut, sharply defined above and below. The bowel involved suffers from compression or occlusion of its blood vessels, and can be easily recognized as a greatly congested and widely distended portion of the intestine. In volvulus neonatorum the extent of bowel involved is so great as to render its recognition difficult. There is obstruction only at one end of the twisted bowel—the duodenal end. The lower extremity in ileum or colon suffers no occlusion. The degree of vascular congestion is slight. Collapse rather than distension is likely to occur, and only the upper duodenum and the stomach become greatly distended. In general the symptoms are those occasioned by duodenal obstruction.

### Symptomatology.

**1. Intrinsic Duodenal Obstruction: Duodenal Atresia and Stenosis.**—*SEX.*—In contrast to the rule in hypertrophic pyloric stenosis, where more than four-fifths of the whole occur in males, boys and girls seem equally affected.

*Prematurity and other Malformations.*—In congenital duodenal stenosis or atresia the infant is not infrequently premature, sometimes the subject of other congenital malformations, yet most often strong, healthy, and well formed in other respects at the moment of birth.

*Age.*—The age of the infant at which serious symptoms first attract attention depends upon the completeness of the obstruction. In the great majority the occlusion is complete, or all but complete, and unless relieved by operation life is not prolonged beyond two or three weeks. Many have died about the ninth day. In only a very few is a painful existence maintained for a few months. Smellie's case lived nearly three months; Buchanan's eighteen months; Cautley's eighteen months; von Koos's thirteen months before operation and two months after. Silcock, Perry and Shaw, and Moore have recorded the accidental finding of duodenal stenosis, thought to be congenital, in the *post-mortem* examinations of adults. In general, in spite of these occasional exceptions, it may be said that if operative interference is to save life the diagnosis must be established within a few days of birth.

*The Vomiting.*—The persistent vomiting of bile-stained fluid in a newly born child should always arouse the suspicion of duodenal obstruction. The vomiting begins upon the first, second, or third day of life, so soon as food is taken in considerable quantities. It occurs with great regularity soon after a meal. Although vomiting is profuse, it lacks the explosive character of the act in hypertrophic pyloric stenosis. In more than 80 per cent. of the recorded cases the vomit is brightly stained with bile. In the remainder, when the obstruction is above the papilla, there may be no bile in the vomit. In the later stages haematemesis is common. Bilious vomiting is rare in hypertrophic pyloric stenosis; I have met with it only once.

*The Stools.*—Some degree of constipation is the rule, but the complete absence of meconium and the passage of only a little glairy mucus, as is the rule in intestinal occlusion at a lower level, do not occur. Generally it is noted that on one or more occasions a little meconium, not very abnormal in appearance, has been voided, but that as the days pass there is no sign whatever of the usual change to yellow milk stools. In hypertrophic pyloric stenosis the change to milk stools always takes place in the usual way, although at the height of the disturbance the stools may again assume a character which reminds one of meconium—that is, they become the slimy, deeply pigmented stools of complete inanition. Microscopic examination, in cases of complete obstruction, may show the absence of lanugo.

**The Examination of the Rectum.**—In duodenal stenosis or atresia the examining finger encounters nothing very abnormal in the rectum. In occlusion of the lower alimentary tract the rectum and pelvic colon are often quite undistended, so that the finger cannot be passed more than 2 or 3 inches from the anus. It is to be remembered that rectal atresia is always situated within 2 inches of the anus, so that confusion should not arise. In several instances the inability to pass the finger into the rectum has led to the erroneous diagnosis of a rectal rather than an intestinal atresia. For the same reason in an ileal or colic obstruction it is usually possible to inject only minimal amounts of fluid into the bowel. In duodenal obstruction, on the other hand, the same difficulty is less likely to be encountered.

**The Abdomen.**—In duodenal obstruction the abdomen seldom shows any general distension. Only the epigastrium may be full and the outline of the stomach, with faint indications of peristaltic activity, may be apparent. Immense peristaltic waves, such as gradually develop in the later stages of hypertrophic pyloric stenosis, are not seen. On the other hand, it is important to notice that the visible peristalsis may be appreciable in the first days of life, while in hypertrophic pyloric stenosis it develops slowly after an interval, usually of some weeks. In intestinal occlusion at a lower level the abdomen may be greatly or irregularly distended, and visible intestinal peristalsis rather than gastric peristalsis is the rule. Auscultation over the distended abdomen will often disclose a great variety of loud gurgling sounds and borborygmi, while in duodenal obstruction there is unusual silence.

**The General Condition.**—After the first few days of life emaciation and dehydration proceed rapidly. Soon the temperature becomes subnormal, the extremities cold and cyanosed, and the pulse rapid. The facial expression is anxious and the child looks very ill, contrasting with the eager, alert, if pained, expression of the baby with hypertrophic pyloric stenosis. Anuria is common. Many are jaundiced more deeply than is the rule with the newly born.

**The X-ray Picture.**—In nearly all cases an x-ray examination after a bismuth meal will show a quite characteristic picture, which can hardly fail to make the diagnosis clear. The duodenum is seen as a widely distended pouch, ending abruptly at the site of the obstruction. By an x-ray examination, and by careful clinical examination, it ought to be possible to avoid confusion with intestinal occlusion at a lower level, in which constipation and the abdominal distension rather than the vomiting are the prominent features. For this reason I have excluded consideration of ileal and colic atresia.

The following case, which came under my care in the children's department at Guy's Hospital, is an example of congenital duodenal stenosis, with complete or almost complete obstruction.

The baby, a girl, weighed at birth 3½ lb. She was a first child, born after one miscarriage. On the first and second days nothing occurred to arouse anxiety. On the third day vomiting began, and continued with increasing severity after every breast feed. The vomit was deeply bile-stained. The baby was seen by me on the fifth day. I was told that up to that time the bowels had opened twice and a little meconium, not noticeably abnormal. There was no visible peristalsis of the small intestine, and although close inspection seemed to show the outline of the distended stomach no definite peristaltic waves were seen. An examination after a bismuth meal showed a dilated stomach with nothing leaving the pylorus. Thirty minutes later a second examination showed the outline of the greatly distended duodenum (Fig. 1), which ended abruptly at a point apparently in its second part. Two small opaque spots below suggested that a small amount of the meal had passed an obstruction which was barely perforate. On this day, the fifth of life, the infant's weight was 16 oz. less than at birth, although very little meconium had been passed. That

afternoon Mr. Steward performed a posterior gastro-enterostomy. There were a few ounces of straw-coloured fluid in the peritoneal cavity, but no other evidence of peritonitis. The site of obstruction was marked outside the gut by a paler area, perhaps half an inch long, above which the bowel was greatly dilated and engorged, while below it was collapsed and empty.

For the first six days after operation bilious vomiting continued, although in decreasing amount. The bowels were open on the day after the operation. Three weeks after the operation x-ray examination showed the opaque meal issuing from the stoma, while the distended outline of the duodenum was still apparent.

On the twenty-fifth day after the operation the child was sent home, weighing 8 lb. 5 oz. When 3 months old, during hot weather, the infant suffered severely from an attack of diarrhoea and vomiting, and, as might be expected from the conditions produced by the operation, the vomited matter was bile-stained. Fig. 2 is a photograph of this baby, now apparently healthy, at the age of 8 months.

FIG. 1.—Congenital duodenal stenosis, showing dilatation of upper duodenum.

Pélu and Auberge, who have recently exhaustively reviewed the literature of duodenal obstruction in childhood, divide the cases into two groups: cases of stenosis and atresia, here called "intrinsic," which they term "cases incompatible with existence"; and cases, here named "extrinsic," which they call "cases compatible with existence." I have recounted this success in detail because I feel that the view implied in this nomenclature is altogether too gloomy. *Post-mortem* records show a very large number of cases which almost certainly might have been saved in the same way had the diagnosis been established in the first days of life by means of the characteristic x-ray picture.

In the literature, however, only one other case is reported as having been saved by timely operation. In 1916 Ernst of Copenhagen successfully performed duodeno-enterostomy, which would appear to be the operation of choice in a case of duodenal atresia.

**2. Extrinsic Duodenal Obstruction: Abnormalities of Intestinal Rotation, etc.—Age.**—The symptoms in extrinsic cases are often less complete and less characteristic. The history in general is one of recurrent attacks or bouts of severe vomiting of bilious material, together with abdominal pain, dating back in many cases to earliest infancy, but often beginning in later life. It is clear that the anomaly of intestinal rotation and of peritoneal fixation can be present without producing any obstruction, but that it does powerfully predispose to a variety of accidents, such as volvulus, ptosis, and kinking of the duodeno-jejunal flexure, or duodenal obstruction by peritoneal bands and by

the superior mesenteric artery as it passes into the root of the mesentery.

Of twenty-eight cases of duodenal obstruction of this variety recorded in the literature as being relieved by operation, and reviewed by Duval and Gatellier, in six the subjects were children. Dubose's case was 8 weeks old, Frank's 11 months, Downes's 4½ years, Ombredanne's 11½ years, Kotzareff's 12 years, and Foisy's 14 years. Rixford has recorded successful reduction of volvulus at 5 years of age. Poynton

has recently published four cases in children occurring within a short time of each other in his own practice, all of which, however, proved fatal. Since all the characteristic features of a localized intestinal volvulus are absent, he rightly emphasizes the likelihood of confusion with that more common cause of bouts of uncontrollable vomiting in childhood, the so-called cyclical vomiting.

In very many cases, however, it would appear that the first attack of duodenal obstruction is fatal. Of Dott's series of thirteen cases in which duodenal obstruction had occurred, collected from the literature, symptoms developed within a few days of birth in six. In his own two cases the infants died on the twelfth and sixth days of life, immediately after an unsuccessful attempt to reduce the

FIG. 2.—Photograph of the infant with congenital duodenal stenosis taken when aged 8 months.

obstruction by operation. Of the four cases published in 1923 by Jewesbury and Pago, occurring in young infants admitted to St. Thomas's Hospital within a short time of each other, one was an example of atresia and one of extrinsic duodenal obstruction by arterial pressure. Both of these died. Two others, in which the extrinsic obstruction was by kinking of the duodeno-jejunal flexure by peritoneal bands, were saved by operation. I agree with Dott that in all probability extrinsic obstruction is more common in the newborn than is generally supposed. Such cases are sure to be confounded with dyspepsia and treated by dietetic prescriptions. The danger to life must vary with the precise nature of the accident to which the obstruction is due. It is likely to be much greater in volvulus than in obstruction by peritoneal folds or bands.

**Vomiting.**—The vomit is always bile-stained. In the later stages haematemesis may occur. The act follows closely upon the intake of food.

**The Stools.**—Meconium is voided normally after birth, and if the onset of the obstruction is delayed for some days the change to milk stools may take place normally. Later, constipation will be severe and the stools become those characteristic of a state of inanition.

**The Abdomen.**—Distension will only affect the epigastrium, where the outline of the stomach and perhaps gastric peristalsis may be dimly apparent.

**The X-ray Picture.**—The diagnosis is only likely to be made with certainty by means of an x-ray examination. It must be directed to the elucidation of two points. Normally the duodenum empties with great rapidity. For a few seconds, perhaps five or six, the issuing shadow will be seen to pause in the first part of the duodenum immediately beyond the pylorus. The remaining parts of the duodenum are traversed in the space of six or eight seconds more. In extrinsic duodenal obstruction in older subjects the duodenum is seen to be greatly dilated, and to empty with difficulty and very slowly. Peristaltic waves are observable, and sometimes reverse peristalsis with return of the food through a "forced" pylorus. In infants something of the same may be seen, if perhaps in less developed form. Secondly, in cases of doubt attention should be paid to the position of the caecum and ascending colon. If there is a left-sided caecum, or if it is otherwise abnormal in situation or unduly movable, the probability that we are dealing with a case of obstruction from abnormality of peritoneal fixation is greatly strengthened. For this examination a bismuth enema is valuable. Such an examination in an older child may be necessary to distinguish the condition from one of cyclical vomiting.

Dott has discussed the operative procedure indicated if laparotomy reveals a neo-natal volvulus. The pressure can be relieved by the reduction of the volvulus, as was successfully done in Rixford's case. Dott favours the delivery of the intestines and their rapid untwisting, deciding in each case whether to return them in the position of malrotation or to complete the rotation to the normal position by hand. He advises fixation of the caecum as an additional security against recurrence. If on account of adhesions reduction is impossible, a gastro-enterostomy should be performed. In obstruction by peritoneal bands it may only be necessary to free the duodenum from their pressure.

#### B. OBSTRUCTION OF THE PYLORUS.

True organic stenosis at the pyloric valve from congenital defect is occasionally found in adults. Landerer in 1879 and Maier in 1885 were the first to record a series of cases of this defect which had in common an absence of the ring-like thickening due to the musculature of the pyloric sphincter, while the mucous membrane passed inwards at the point to form a valve-like diaphragm pierced by a quite small opening. In Landerer's cases the pyloric canal and stomach showed dilatation, but little or no hypertrophy. Maier described at least one similar case without hypertrophy, but added a large number in which, in addition to the valvular obstruction, there was present a considerable hypertrophy of the muscle of the whole pyloric canal and pyloric part of the stomach. It seems likely that cases in adults of pyloric stenosis and hypertrophy described by Maylard, Barling, and others in this country and thought to resemble the common hypertrophic pyloric stenosis of

infancy, were in reality of the type described by Landerer and Maier in Germany and recognized by Russell in this country. It is interesting to recall that Hirschsprung, in calling the attention of the profession to the common hypertrophic stenosis of infants, made the opposite mistake, and was at first under the impression that he was recording cases in infancy of the organic stenosis of the type described by Landerer and Maier. In hypertrophic pyloric stenosis there is present, of course, no true organic stenosis at all. Within the rigid spastic musculature of the pyloric canal there lies a lumen in every way normal, but so folded that on transverse section the outline appears shaped like a star or rosette. Since Hirschsprung's first communication innumerable cases of hypertrophic pyloric stenosis have been encountered and recorded, and the great frequency of the condition is now fully appreciated. On the other hand, even among adults the records of cases of organic stenosis remain very few. In infancy, I know of but one undoubted case, that described by Schäfer. It is characteristic of this form of pyloric obstruction that the symptoms begin at some time during later childhood, but not during infancy.

Schäfer's post-mortem examination showed closure of the pylorus by a membranous diaphragm composed of mucous membrane with a central lumen which permitted the passage of only a very narrow sonad. During life a litre of malted milk had passed the obstruction daily without giving rise to any appreciable discomfort. A most minute examination showed no trace of the pyloric ring sphincter muscle, but in its place a fold of mucous membrane; this was confirmed by histological examination.

Faber has recently reviewed the literature; it may be remarked that the condition seems almost completely to have escaped attention in this country.

I am unable to add to the single observation in an infant accidentally made by Schäfer, but I show two specimens from adults typical of this congenital hypoplasia of the pyloric ring muscle.

The first is the stomach from a man 38 years of age, who had suffered from the age of 12 with abdominal pain, vomiting, and tetany, of great severity. He came under the care of Dr. Fawcett, to whom I am indebted for the specimen, but died suddenly before operation could be undertaken. The stomach is very greatly dilated. The pyloric canal has been distended and taken up into the body of the stomach, much as the cervical canal is taken up by the pregnant uterus at the commencement of labour. Separating the small duodenum from this huge stomach is a membranous diaphragm, perforated by a small aperture.

This man's father, who also came under Dr. Fawcett's care, suffered apparently from a similar defect of development. At the age of 63 he too was admitted for attacks of abdominal pain and vomiting of "fifty years' duration." At times as much as nine pints of fluid had been removed from the stomach by the pump. The state of his kidneys, however, made operation inadvisable.

I show also a specimen from the museum of Guy's Hospital, of which I think the description in the catalogue is misleading. It shows the pyloric end of a very greatly dilated stomach, which measured 30 in. by 9 in., from a man, aged 38, who had suffered with symptoms of pyloric obstruction since the age of 12. The specimen shows the same hypoplasia of the pylorus, with a fold of mucous membrane in the form of a diaphragm, perforated by a small central aperture.

It is, I think, clear that these two specimens, so alike in every detail, both in their clinical history and in their post-mortem appearances, are examples of the congenital pyloric stenosis of the type described by Landerer and Maier.

#### ŒSOPHAGEAL OBSTRUCTION.

In order to complete the list of causes of persistent vomiting in infancy due to anatomical defect, it is necessary to say a word as to the condition of oesophageal stenosis or atresia. Cautley has recently reviewed the literature so exhaustively that there is little that can be usefully added.

**Etiology.**—A study of the developmental defects which involve the oesophagus entails also a study of similar defects in larynx and trachea.

Keith has discussed the results of abnormality in the development of the tracheo-oesophageal septum. De Vries of Amsterdam has figured diagrammatically the possible results of failure of this septum to develop normally, and has found in Continental literature cases recorded which illustrate every variety. By far the most common form is that in which atresia of the oesophagus is combined with an opening between the lower oesophagus, below the atresia, and the trachea. The opening may be wide or it may be narrow. A similar atresia or stenosis

of the larynx with a communication between the normal oesophagus and the lower trachea or a bronchus is also encountered. On the other hand, atresia of oesophagus without communication with the trachea is very rare. Atresia or stenosis of larynx without communication with oesophagus may also occur. A small fistulous communication between the two passages, due to developmental error, may be present without other defect, or it may complicate the more usual oesophageal atresia. Traction diverticula may represent such a fistulous communication in an incomplete form.

**Symptoms.**—In the form most frequently met with—oesophageal atresia, with communication between the lower oesophagus and the trachea—death invariably follows within a few days. The child, though sucking strongly and hungrily, is able to swallow only the first few mouthfuls; thereafter the attempt to swallow leads to a free regurgitation from the mouth and the nose. The attempt to take food; moreover, has commonly to be given up because of asphyxial attacks or attacks of choking and coughing. A sound is held up, very often at a distance of some 10 cm. from the gums. The shadow of an opaque meal shows clearly the obstruction in the oesophagus. Death is commonly from an inhalation bronchopneumonia, due to the fistulous opening between trachea and the lower segment below the obstruction. In a few cases the respiratory movements have served to bring about great inflation of the stomach with air which has passed along the same route. The existence of this communication serves to make even the desperate expedient of gastrostomy useless and inadvisable.

In oesophageal obstruction the regurgitation of the milk is so clearly due to a failure to swallow that the condition can hardly be confused with any other. Even in diaphragmatic hernia, with the stomach within the thoracic cavity, the difficulty does not concern the act of swallowing, although here again we may meet with asphyxial attacks which are produced by the attempt to take food. In oesophageal stenosis, as distinct from atresia, symptoms are seldom prominent during infancy while the diet remains fluid. The cases present themselves for examination in later childhood.

## PUERPERAL SEPSIS IN WALES.\*

BY

SIR EWEN MACLEAN, M.D., F.R.C.P.,

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE.

THE tables and diagrams exhibited, taken in conjunction with those for previous years, show that Wales has a consistently high maternal mortality rate, and that the Welsh figures are much higher than the combined figures for England and Wales. Further, the fact emerges that whilst the "sepsis" death rates are somewhat higher in Wales than in England and Wales, the chief disproportion is from "other causes." I have to thank the Registrar-General for permission to quote the figures in the table relating to 1923, which have not yet been published.

*Distribution for Wales and for England and Wales of Mortality of Women in Childbirth, per 1,000 Children Born Alive, distinguishing Septic and other Causes, 1921, 1922, and 1923.*

The three types of population compared are—

- (1) County borough populations, which are truly urban in character.
- (2) Other urban districts, which contain a large number of people living under semi-rural conditions.
- (3) Rural districts, the bulk of whose populations are country dwellers.

It will be seen that in England and Wales as a whole the death rate from sepsis is lowest in rural districts, and becomes higher proportionately as the urbanization of the population increases. With regard to the death rates from "other causes," the position is reversed. The more highly urbanized populations show the lowest maternal mortality from "other causes." This may be attributable to the better medical and surgical facilities available and to the provision of maternity beds.

In Wales the sepsis death rates show no regular variation with the type of population concerned; but regarding deaths from "other causes," the table shows how much greater is the risk for the rural mothers than for the mothers in the urbanized communities.

The first report of the Welsh Consultative Council draws attention to the fact that Wales is a rugged and mountainous area, consisting for the most part of rural counties sparsely populated, with exceptional difficulties

\* Paper preliminary to a discussion on puerperal sepsis at the British Congress of Obstetrics and Gynaecology, London, April 22nd.

in intercommunication, and also containing some very congested industrial districts where the population has accumulated within recent years with a rapidity that has created unfortunate conditions for the amenities of life and the health of the people. A special feature of importance is the marked contrast in population distribution existing between, on the one hand, the area covered by the geographical counties of Glamorgan and Monmouth, and, on the other hand, the area covered by the remaining eleven counties. The estimated population of Wales in the recent census (1923) is 2,704,000 in round figures. Of this total 1,765,000 reside in the geographical counties of Glamorgan (1,298,500) and Monmouth (466,500). Thus approximately two-thirds of the entire population of Wales live in two geographical counties, the remaining one-third being spread over eleven counties, the average population of which is only 85,000 (round figures).

We have sent in from the maternity department of the Cardiff Royal Infirmary our quota of records of puerperal sepsis, and these have been merged in the consolidated report of the Obstetrical and Gynaecological Section. Apart, however, from the purely clinical and laboratory aspect of the subject, I venture to offer to the Congress some observations, arising out of certain visits of inquiry, made to some seven or eight centres in the Principality during 1923-24. On four of these occasions—one in North and three in South Wales—I was accompanied by some colleagues of the Council and of the Welsh Board of Health, and it was a special advantage to meet the medical officers of health (county and district) and representatives of health committees, nursing associations, practising midwives, insurance committees, voluntary organizations, and others interested in general health questions. The conference was held in the morning, and in the afternoon the doctors of the area attended in goodly numbers, and a frank and unfettered discussion ensued. Nothing was more striking than the keen desire on the part of the members of the profession and of the various bodies represented and concerned to bring about a betterment in the mortality and morbidity rates associated with childbirth and childbed. I will endeavour to indicate some of what appear to me to be the more important facts emerging and impressions gained at these local inquiries.

1. *Locality.*—As between rural, industrial, and mixed areas it would seem that the incidence of maternal mortality from puerperal sepsis is not demonstrably influenced to an appreciable degree by geographical location or by questions affecting distribution of population.

2. *Midwives.*—Although some medical practitioners consider that the old bona-fide midwife was more likely to send for medical help on the occurrence of difficulties, the opinion of the doctors generally, as well as of the various representatives, was strongly in favour of a larger supply and a more satisfactory distribution of fully qualified midwives. It was agreed that such a distribution might be effected on lines which allowed of a reasonable degree of freedom of choice by the patients and satisfactory sharing of the work by the midwives. A systematic distribution should also provide, by substitution or otherwise, for the contingency of midwives becoming "contact" with septic or other infective conditions.

3. *Midwives, Health Visitors, and District Nurses.*—It was generally agreed that, subject to satisfactory distribution, the midwives should be restricted to the practice of midwifery, but that where this was not practicable—for instance, in some rural areas—it was preferable to combine the duties of the midwife with those of the health visitor rather than with those of the district nurse.

4. *Home Helps.*—Some divergence of opinion was evident as to the feasibility of establishing the status of what are called "home helps" in any health scheme. The really efficient home help must represent a consolidation of good qualities rarely seen.

5. *Maternity Homes, Maternity Wards, and Ante-natal Clinics.*—The value of these was fully recognized at the conferences in all the centres visited. In certain areas local opinion had to be educated as to the essential value of these establishments in order to lead to their being freely used. Prejudices in regard to the work of the trained midwives and health visitors had at first existed,

but had in large measure disappeared, and the evidence went to show that where lying-in beds and ante-natal clinics had been made available a similar experience had accrued. To have the ante-natal clinic within the curtilage of the maternity hospital had been found to be a convenient and educative arrangement. In the larger towns it had been found of great advantage to link up the maternity ward or wards with the general hospital, so that the service of the medical, surgical, and special departments would, if required, be available for the expectant or parturient mother. The importance of the medical officers of the ante-natal clinics keeping in touch with the general practitioners and advising them of any abnormality discovered was strongly emphasized, and in midwives' as well as doctors' cases the value of periodic examination of the urine during pregnancy was readily conceded.

6. *Mothers' Teeth.*—In the rural areas, especially, care of the teeth during pregnancy was little thought of, and the adage "for every child a tooth" had been expanded into the prevalent belief that in the expectant mother dental caries was inevitable and its treatment undesirable. At one of the inquiries a medical officer of health stated that the condition of the mouths of the mothers who attended the infant welfare centres was "appalling"; and at another a medical practitioner said that the condition of the teeth of the people generally was very bad—"that no woman ever thought of going to a dentist unless she had toothache, and that there was a fallacious general belief that women ought never to have their teeth attended to by a dentist during pregnancy." In the rural areas there is difficulty in obtaining the services of qualified dentists.

7. *Nourishment of Expectant Mothers.*—In the more rural areas the inquiries went to show that the general standard of living of the mothers was very poor, and their dietaries inadequate and badly balanced. It was stated that in the smaller homes families seldom saw a joint of fresh meat; that milk was often unobtainable; that the people had not acquired a taste for fresh vegetables which could so easily be grown; and that they seldom had any form of fresh food. The family fare consisted too largely of tea and bread-and-butter—"the teapot never gets cold till late at night"; and the tendency, even where produce was grown, was to sell the best of everything and keep the poorest for consumption at home. Statements were made to the effect that, even in these circumstances, the mothers by their own act "came last," and were often markedly anaemic and debilitated, with the result that at the time of confinement their powers of resistance, whether in regard to infection or other parturient risks, were at the lowest ebb. In the industrial areas the unselfishness of the mother was an important factor, especially under the present economic conditions, both as regards improper and insufficient dietary and also as regards the strain of the almost continuous household duties—in the colliery districts, for instance, where the husband, sons, and lodgers may be engaged in different work shifts at the pits.

8. *Housing Conditions and Environment.*—Much evidence was forthcoming to show the need for a more enlightened public opinion as to the capital importance of sanitation and other hygienic conditions. Apart from the admitted shortage of housing accommodation, the dilapidation of existing houses, and the existence of overcrowding, which are unquestionably contributory factors in the problem, there remains the fact that even in present conditions there is scope for much improvement in the habits and customs prevailing in many parts of the country—improvement that can only be achieved by a vigorous educational effort by health authorities and all who are interested in bringing about a fuller appreciation of the laws of health—both by those who build the houses and by those who live in them. In the country the houses are often very small and badly ventilated. Many of the cottages consist of two rooms with a loft, and the flooring may be of mud or sometimes slate. As many as 20 per cent. of the houses have no sanitary arrangements whatsoever. There is too often a lack of personal and household cleanliness and a general disinclination to change personal or bed clothing. Occasionally women may be confined on the floor, lying on clothing already soiled, to save the bed. In the industrial areas there is a great deal of overcrowding. In the Rhondda district over

10,000 families live in houses occupied by more than one family, and in this and other areas instances were quoted where two or more families lived in the same house, and that of small dimensions, with the result that confinements had often to take place under the most undesirable and unseemly conditions. The plea for the establishment of maternity homes and hospitals in such areas is overwhelming, but the response is slow.

**9. Non-disclosure of Puerperal Sepsis.**—Either avoidably or unavoidably, the requirements with regard to notification are not properly observed. For the five years 1918-22 inclusive, while there were 503 deaths from puerperal sepsis in Wales and Monmouthshire, the number of notifications was only 579, and in some areas the number of deaths exceeded the notifications. This important matter was fully discussed at all the meetings with the doctors, and there was general agreement that, notwithstanding the disabilities in the practices of doctors and midwives which might accrue from notification of sepsis, the urgency of taking all steps to prevent the spread of the infection, as well as to secure such help in the management of the case as the local authority could furnish, should prevent the avoidance of this responsible duty.

**Diagnosis.**—At the same time many of the practitioners drew attention to some real difficulties. First, as to diagnosis, it was fairly stated that, apart from pyrexial conditions which are quite independent of the puerperium as such, and excluding also the so-called "reactionary" rises in the first twenty-four hours, temporary elevations of temperature from 100° to 102° F. may occur during the first week from errors of diet, constipation, emotion, or other nervous disturbance, or from unimportant mammary conditions. More guidance was asked for in regard to differential diagnosis.

**Notification.**—As desiderata it would appear to be considered that either a readily applied clinical test should be evolved or a more comprehensive formula employed as the basis for notification. The difficulties might be that with the former not a few cases of sepsis would escape detection, and that the latter would include more than all the cases of infection. At one of the meetings a recommendation was made indicating the desirability of district medical officers arranging with registrars of births and deaths of the sub-districts for the supply of earlier information of deaths caused by puerperal fever, as this would enable the medical officers of health concerned to make prompt inquiries as to actual and contributory causes. Another handicap to notification was the objection sometimes raised by the lying-in woman herself or by her relatives and friends. Notification which results in nothing beyond visitation by various officials cannot be other than unpopular, but if and when it is followed by helpful service and, where necessary, institutional treatment, the prospects of its acceptance and efficiency are more assured.

**"Brad-gyfarfod."**—Complacency is another contributory cause to inefficiency. This was especially illustrated by the discovery in one of the rural counties of the tradition that a mother recently confined must have a rise of temperature, the condition being dignified by the title "brad-gyfarfod," which, freely translated, may be taken to mean "a combative meeting," the factors in the combat being regarded as the lochia and the mammary secretion. It is not contended that such a belief is generally current, but it would certainly be true to say that the existence and even the persistence of a temperature in childbed is far too often regarded by the patient and her friends with the minimum of concern.

**10. Attendance by Doctors and Midwives.**—There is considerable diversity in various parts of Wales in regard to the number of confinements attended by midwives only and the number attended by doctors (with or without midwives). Thus, in Merionethshire—a rural county—the proportion of cases attended by doctors is very high, the figures being 18 per cent. attended by midwives only and 82 per cent. by doctors (with or without midwives). At the other extreme, in the Rhondda district (Glamorgan) 81 per cent. were attended by midwives only and 16 per cent. by doctors (with or without midwives). Speaking generally, these variable proportions, as between rural and industrial areas, prevail throughout Wales and Monmouth-

shire. It would be fallacious to infer from these proportions that the rates of morbidity and mortality follow in either one direction or the other. Fears were expressed in some of the industrial areas that the high proportion of cases attended by midwives was disadvantageous to the patients, but on the whole it was found that in these areas the midwives are well trained and sufficiently impressed with the importance of sending for medical aid as occasion may require. In the rural areas the dearth of trained midwives accounts for the large proportion of cases in which the doctor is engaged, and it is claimed, too, that the unskilled services of the handy-woman contributed largely to the high sepsis rate. It was agreed that an increased supply of qualified midwives is especially urgent for the rural areas.

**11. Ages of Marriage.**—In the counties of Wales and Monmouthshire a comparison of the percentage of the total marriages of women contracted (1) before the age of 21, and (2) after the age of 35, shows that in 1921 there was a higher percentage of early marriages in Wales (18.2) than in England and Wales (14.9), and a lower percentage in the later marriages (Wales 9.3, England and Wales 10.7). It is significant that some of the counties showing the highest percentages of late marriages are also amongst those with the highest maternal mortality rates.

**12. Abortion.**—The impression was gained that abortion and attempted abortion, both by means of drugs and various instruments, is prevalent to a considerable and an increasing degree in the industrial parts of Wales. In one such area with Pontypridd as its population centre the figures show that 11.5 per cent. of the deaths arising out of pregnancy and childbirth were attributed to this cause.

**13. Use of Forceps.**—The question of the use and abuse of the forceps was fully and frankly discussed at the doctors' meetings. There was common agreement in the view that, whilst in a proportion of cases the use of the forceps was advisable or imperative, in no case could the mere saving of time of those in attendance be regarded as a justifiable indication, having regard to the admitted increase in the risks of infection and injury which their employment entails. As to the use of forceps generally, not a few of the doctors claimed that they applied them much less often than was their habit some years ago, and that this was, in part at least, attributable to the good results of ante-natal clinics as well as to pronouncements of some latter-day obstetricians.

**14. Rubber Gloves and Sterilized Obstetrical "Outfits."**—The doctors and the representatives of the midwives concurred in the view that the intelligent use of rubber gloves and the provision of sterilized "outfits" would do much to combat those domestic conditions which so largely increase the risks of septic infection.

**15. Notification of Pregnancy.**—Compulsory notification, however valuable it might be as leading to adequate supervision during pregnancy, was regarded by all parties represented at the various conferences as impracticable. It was thought, however, that the principle of voluntary notification would ultimately prevail when, by wise propaganda and the continued advice of doctors, midwives, and health visitors, the benefits deriving therefrom were more generally appreciated.

#### Summary and Conclusion.

The facts and responsible opinions emerging from these representative conferences justify the conclusion that the efforts which the community must make toward the solving of this urgent problem must include the following:

1. A more complete and better organized provision of thoroughly well trained and suitably educated midwives and health visitors.
2. A considerable extension of well supervised schemes for the ante-natal supervision of mothers, both domiciliary and at clinics.
3. An extended and improved supply of milk and other necessary forms of nourishment for expectant and nursing mothers.
4. A very substantial addition to the existing provision of maternity homes and of maternity wards in or in connexion with the general hospitals.

Finally, I am convinced that by better organized clinical and laboratory research such further light can be thrown

upon the predisposing and the actual causes of puerperal sepsis as will lead to a much larger measure of prevention and to more effective treatment, and there can be little doubt that a very real contribution to that end will be reckoned among the many good results of this Congress.

## A CLINICAL AND BACTERIOLOGICAL INVESTIGATION OF PUERPERAL FEVER IN THE ROTUNDA HOSPITAL, DUBLIN.\*

BY

GIBBON FITZGIBBON, M.D., F.R.C.P.I.,

MASTER, ROTUNDA HOSPITAL;

AND

JOSEPH W. BIGGER, M.D., F.R.C.P.I.,

PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF DUBLIN.

THE 57 cases of acute puerperal fever considered in this paper were treated in the Rotunda Hospital during the past four years. The deaths numbered 23 (51 per cent.). Fifteen cases developed amongst patients wholly treated in the hospital and 9 died; 25 developed in the hospital district and 7 died; 17 were patients sent into hospital either late in labour with complications, or after delivery with fever, having been previously treated but not in the hospital district, and of these cases 13 died.

### INCIDENCE OF INFECTION.

During the four years 14,380 confinements were attended—6,810 in the hospital and 7,570 in the hospital district—and of these 40 appear as acute puerperal sepsis, with 16 deaths; this gives an incidence of infection of 2.8 per 1,000 and a mortality of 1.1 per 1,000. Of the hospital cases, 25 were spontaneous deliveries, 2 were simple low forceps, and 1 a breech; of these 28 cases 8 died. Two cases were first seen after complete abortions, and both died. Of the remaining 10 cases Caesarean section was performed in 2 and pubiotomy in 1, secondary post-partum haemorrhage occurred in 1, and in 6 manual removal of the placenta was practised; of these 6 died.

Three cases were almost certainly not of genital origin.

Case 1 was spontaneously delivered and had returned home after a perfectly normal puerperium; on the eleventh day she suffered from retention of urine, and had to be relieved by catheter; on the fourteenth evening she had a rigor, and died seven days later. The history suggests that infection occurred at the time of catheterization.

Case 2 died of acute endocarditis; her morbidity started with acute tonsillitis; laparotomy was done on the twenty-second day and the peritoneum and pelvic organs found normal. Uterine swabs were persistently sterile.

Case 3 had been seriously ill with rigors and high fever for several days before labour; she was confined prematurely of a macerated foetus, and died of acute endocarditis. The only reason for suspecting a genital origin in these two cases was the removal of the placenta manually.

Excluding these three cases, there remain 27 infections after normal deliveries, with 7 deaths; and 8 infections after complicated labours, with 4 deaths. Among 17 cases sent into hospital on account of difficulty or complications previously treated, 13 deaths occurred; omitting 4 cases that ended in spontaneous delivery, although 3 died, there are 13 seriously protracted labours followed by infection, with 10 deaths. Although the incidence of infection amongst cases wholly treated in the hospital is only 2.2 per 1,000, compared with 3.3 per 1,000 cases attended in the hospital district, the mortality in the hospital is 1.3 per 1,000, against 0.9 per 1,000 in the district.

### Conclusions.

The incidence of acute puerperal infection should not reach 1 per 1,000. It must be recognized that complicated cases met with in the district are sent into hospital early for treatment.

Any interference in labour, other than low forceps over the perineum and simple laceration of the perineum, considerably increases the incidence of infection and the resulting mortality.

Impacted labour, particularly with devitalization of the pelvic tissues and debilitating haemorrhages, increases the incidence more than any other cause, and the resulting mortality is very great.

### SOURCE OF INFECTION.

There has never been any traceable connexion, by vaginal examination, between two cases in the hospital or in the district, but there have been suspicious instances of a second case developing while another was under treatment, although there has not even been ward contact.

Table showing Nature of Infecting Organisms.

	Cases.	Deaths
Haemolytic streptococci ...	32	14
Non-haemolytic streptococci ...	8	4
Anaerobic streptococci ...	1	1
Streptococci not classed ...	6	1
Gram-positive cocci (smears only examined) ...	3	2
<i>Bacillus welchii</i> ...	1	1
Cases not examined ...	6	6

There is little reason to suppose that the three unclassified cocci were other than streptococci, or that the six fatal cases not examined would have varied from those examined. One case gave *Staphylococcus aureus* from the uterus, but haemolytic streptococci from the heart and lungs post mortem.

### Conclusions.

From these and other observations\* it may be concluded:

- (1) That acute puerperal infection is almost invariably due to streptococci, most commonly haemolytic.
- (2) That cultures made from the interior of the uterus during the puerperium are of the greatest possible value in diagnosis. Material should be cultured within a few hours if a negative result as to streptococci is to be accepted.
- (3) That blood cultures are a further assistance if they are positive, but when negative do not exclude serious infection.
- (4) That when haemolytic streptococci are obtained from any part the prognosis is most serious, and probably the infection is always exogenous in origin.
- (5) That non-haemolytic streptococci from the uterus is serious, and from the blood most serious.
- (6) That non-haemolytic streptococci from the uterus, the blood, or from the uterus and blood, is probably often of an extragonital origin.
- (7) That negative results for streptococci from the cervix may usually be accepted, provided the culture is not dominated by other organisms.
- (8) That cultures from the blood positive to either haemolytic or non-haemolytic streptococci are equally serious, but neither is necessarily fatal.
- (9) That *Staphylococcus aureus*, *Bacillus coli*, and gonococci are likely to produce local infections, but do not tend to become general.

### CLINICAL MANIFESTATIONS.

#### Onset of Fever and Period of Invasion.

Of the 57 cases recorded, 24 had a sudden onset, in 6 with rigor and 2 with profuse sweating, the previous temperature having been perfectly normal; 4 had a sudden rise, 2 with rigor, and preceded by slight elevation; 4 had a gradual rise to a high level. The remaining 25 all had elevation of temperature ante partum, from delivery, or within thirty-six hours after delivery, except 7, who were in collapse when delivered or first seen and died without rallying, and 2 others who developed high temperatures when they recovered from the primary collapse.

\* Abridged text of a paper preliminary to a discussion on puerperal sepsis at the British Congress of Obstetrics and Gynaecology, London, April 22nd.

\* Omitted here.

Of the 28 cases with a sudden rise, one had protracted labour requiring pubiotomy, in 2 the placenta was removed manually, one had late post-partum haemorrhage, and in one the presentation was a breech; otherwise the labours were easy. In 21 cases the onset was on the third or fourth day, and in 4 on the second day. The cases with a gradual onset were all easy deliveries. The 25 cases with elevated temperature from or before the first day include only 6 cases with easy deliveries, but 2 of these were abortions, one had post-partum haemorrhage, and one had innumerable vaginal examinations, leaving only 2 easy deliveries not interfered with. In several of these cases collapse temperature, with very rapid or imperceptible pulse, developing shortly after delivery and persisting to death, was the only indication of infection. In such cases the peritoneum will invariably be found infected, without any reaction or symptoms. Professor Crichton of Capetown reported that, having seen an observation on this subject in the last Rotunda report, he had a blood culture made just before death in a case of unaccountable shock following delivery by craniotomy, and found pure haemolytic streptococci. The fact has been established in the Rotunda Hospital, not only in maternity cases that have been tested, but also in gynaecological cases dying of apparent post-operative shock.

#### Conclusions.

That the incubation period of acute puerperal sepsis is probably three days.

That when the patient is not debilitated the onset is sudden, sometimes with rigor.

That damage to tissues and debility from protracted labour disguise the onset.

That collapse setting in after delivery and progressing to rapid death is often the only evidence of infection introduced during a protracted labour.

That "labour shock" is never a justifiable diagnosis of the cause of death after protracted labour until infection has been excluded by a cultural examination of a swab from the peritoneal cavity. These cases are frequently the most rapid and virulent type of sepsis.

#### Prognosis.

Rigors occurred in 14 of the 57 cases in the table and in 2 of the 22 morbidity cases. Profuse sweating, which was probably an abortive rigor, occurred in 3 cases. In 4 cases rigor or sweating only occurred at the onset of fever, in 13 cases they were repeated or developed later. Three patients had rigors almost daily for several weeks, and 2 recovered. Six cases with rigors died.

The occurrence of rigors indicates the more serious type of infection, but nothing as to the course likely to be followed. High persistent or remittent temperature with high spikes is always indicative of serious infection. A four-hourly chart is essential to show the characters. In the second week persistent high temperature is bad, but very high spikes are not necessarily of ill omen if the remissions are good. The pulse commonly follows the temperature; when proportionally lower it is good, but when above the prognosis is bad.

The lochia seldom shows change unless after protracted labour, when it may be profuse and is often fetid. Absence of lochia on the second or third day of fever is a bad sign, but change to pus or the appearance of pus after absence may be considered a definite improvement. Necrosis of tissue or even gangrene and puerperal ulcer of the vulva and vagina do not necessarily indicate acute infection. In the absence of necrosis and fetid lochia the involution of the uterus is frequently normal.

#### DURATION.

Taking the duration of the disease from the first evidence of fever until either death or recovery, then 14 cases terminated in the first week; only 3 recovered, the other 11 succumbed to the shock of invasion. In 13 patients the fever persisted for over twenty-two days, and 8 of these finally died; 9 developed secondary conditions such as abscesses, peritonitis, or endocarditis. The remaining 30 cases terminated in the second or third week—20 recovered and 10 died.

#### Conclusions.

The duration of the fever is most commonly ten to twenty days. A number of patients succumb from the intensity of the onset, and this is promoted by protracted labour causing damage to tissue. When a partial resistance is established secondary complications develop and the cases may be very protracted; the prognosis is not improved—it depends upon the site and nature of the secondary developments.

#### TREATMENT.

Acute puerperal fever appears to be due to invasion by an exogenous organism, and the result depends upon the powers of the patient to resist the invasion or establish a resistance to overcome the infection. So far no specific remedy has been found, and dependence must be placed on general tonic treatment. When evidence of resistance appears, as by local formation of pus, benefit will be derived from drainage or removal of the abscess, but removal of tissue will not produce benefit if resistance has not previously developed.

**Antistreptococcal Serum.**—Polyvalent serum was used in 34 of the cases in the table, and 17 died. Of the 24 cases not given serum 10 died. The dose given varied from 20 to 100 c.c.m., most commonly 20 or 30 c.c.m., repeated once or twice. Prophylactic doses of 30 to 60 c.c.m., sometimes repeated in 30 to 40 c.c.m., were given in 16 cases; 5 of these cases are included in the table, and all died; they were all cases of protracted labour treated outside the hospital. The remaining 11 cases did not develop infection, but only 2 were treated outside the hospital. No conclusions can be drawn from these facts, but serum does no harm, and is given as a routine in suspected cases in doses of 30 c.c.m. repeated once or twice.

**Iodine.**—Intravenous injections of 10 c.c.m. of colloidal iodine are given on the same day or the day after serum is started, and repeated in doses of 10 to 40 c.c.m. at twenty-four to forty-eight hour intervals. The results sometimes suggest extraordinary benefit, and the injections are never detrimental.

**Sodium Bicarbonate.**—Intravenous injections of sodium bicarbonate solution (0.9), 20 to 40 ounces repeated once or twice, or given by repeated rectal injections, appear to do good in some cases, especially when the patient begins to show debility.

**Douching** appears to be useless in the symptomless cases, and entails the risk of peritoneal infection directly through the Fallopian tubes, which are quite patent in the unresisted cases. On the other hand, when pus has formed in the uterus a single or even repeated douche is of unquestionable benefit. Also in cases with profuse fetid lochia a simple douche does good; but no attempt should ever be made to remove material with either a dull or sharp curette or even the finger, and a douche is better not resorted to until drainage by sitting up, even out of bed, has been tried and failed. All cases should be drained by free movement and frequent sitting upright.

**Operative Procedures.**—Whenever pus forms it should be evacuated—cellulitic abscesses, above Poupart's ligament, through the vaginal fornices, or even by laparotomy. If multiple abscesses form in the uterus, hysterectomy, vaginal or abdominal, is indicated. If peritoneal fluid forms it should be drained. When there is suggestion of pus formation in the pelvis but the site is doubtful, a laparotomy is advisable, as any site can be reached and the pelvis drained. Until localization has developed operative measures appear useless. All cases that continue into the third or fourth week should be closely watched for local abscess formation.

#### Post-mortem Examination.

In the great majority of the cases that died an examination of the abdomen and pelvis at least was made. With the exception of the cases with sloughing or necrosis of tissue the organs showed little or no change from the normal, beyond anaemia and slight flabbiness. In no case without evidence of reaction were the pelvic veins thrombosed, and thrombosis was absent when looked for in the few cases with pus formation.

# AN INVESTIGATION INTO THE ETIOLOGY OF PUERPERAL FEVER.\*

BY

JOSEPH W. BIGGER, M.D., F.R.C.P.I.,  
PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF DUBLIN;

AND

GIBBON FITZGIBBON, M.D., F.R.C.P.I.,  
MASTER, ROTUNDA HOSPITAL.

WHILE certain cases of puerperal sepsis are due to staphylococci, *B. coli*, or other bacteria, the majority are attributable to streptococci. Of these the greater number are caused by haemolytic streptococci (chiefly *Strep. pyogenes*), but the residue of cases, due to non-haemolytic streptococci (*viridans* type) are sufficiently numerous to deserve consideration.

Infection of the uterus, as of other parts of the body, may be either exogenous or endogenous. There can be no doubt that a true exogenous infection does occur, as is shown by the recorded instances of doctors and midwives acting as carriers of infection. In many cases, however, the possibility of this mode of infection seems to be slight, and it was with the object of throwing light on what may, for the moment, be called spontaneous puerperal sepsis that the investigation here recorded was undertaken. Briefly stated, we sought to discover whether, in the case of normal labours, streptococci were present in the vagina before delivery and in the vagina and uterus after delivery and of what type. All the cases examined were intern patients in the Rotunda Hospital, Dublin, and, as is to be expected, show a higher percentage of abnormalities than would a normal series. In only one, however, was there any evidence of the existence of any septic condition in the body before delivery.

Swabs were taken from the posterior fornix of the vagina either on admission or soon after. In the majority of cases labour had commenced when the specimens were collected. In a small number of cases where, for some reason, a swab was not then taken, one was secured after the rupture of the membranes. This was also done occasionally in addition to the first swabbing. In all cases swabs of the posterior fornix and of the interior of the uterus were taken during the puerperium, usually between the second and the seventh day after delivery.

## Method of Swabbing.

The patient was placed in the left lateral or Sims's position. The vulva was opened and a Sims's speculum passed in to draw back the perineum, thus fully exposing the cervix. The vaginal swabs were then taken from the posterior fornix. For the uterine swabs the external os and just inside was wiped completely clear of discharge. The cervix was then steadied with a clip and was again wiped out with sterile cotton passed well inside and the culture swab passed directly up into the uterine cavity. The swabs were obtained between noon and 2 p.m., so as to be sent to the laboratory for culture at 2 p.m. The first eighteen in the series were taken by Dr. Wyndham Williams and the remainder by Dr. C. Coghlan, who were attending post-graduate courses. To both these gentlemen we are deeply indebted for their co-operation and for their interest in the investigation.

Since the object of the investigation was to determine whether streptococci were present or not, the laboratory technique was different from that used in dealing with swabs from patients clinically suspected of sepsis, in which cases the diagnosis depends largely on whether streptococci are present in significant numbers, the presence of one or two colonies being usually of no importance. Every effort was made to supply any streptococci present with their optimum nutrient material and to prevent any deaths of the bacteria from drying or delay. Cultures were made within, at most, a few hours of the collection of the swabs. We wish to lay stress on this point: our technique was devised to find whether even a single streptococcus was present on the swab examined. Had the swabs been cultured on solid media, as are swabs sent for diagnostic purposes, the result would have been, in the majority of cases, either no growth or a growth of only a few colonies,

and very many of the streptococci actually isolated would have been missed. We satisfied ourselves on this point by carrying out duplicate cultures on solid and fluid media on the first dozen or so swabs. The method we finally relied upon gave infinitely better results than were obtained by the use of solid medium.

## Method of Cultivation.

The basis of the fluid medium used for primary culture was tryptic broth (pH 7.4) to which was added 20 per cent. of sterile hydrocele fluid and 10 per cent. of a sterile 10 per cent. solution of glucose. The swabs were thoroughly washed out in this medium, which was incubated at 37° C. until the following day, when it was examined. The medium is almost a selective one for streptococci of all varieties, and renders possible their isolation from material in which these organisms are scanty and other bacteria numerous. Streptococci may produce a turbidity with only slight deposit, but more usually form a dense deposit, leaving the upper part of the fluid clear. This deposit was examined microscopically, and if streptococci were seen the result was noted as positive. At the same time the average number of cocci in each chain was recorded. A loopful of the deposit was plated on human blood agar, and the plates incubated for twenty-four hours. Colonies believed to be of streptococci were then subcultured into glucose hydrocele broth, which was incubated until the following day. In many cases two or more colonies were picked where these presented differences visible with a hand lens. The glucose hydrocele broth cultures were examined for purity and to determine the morphology of the streptococci, and subcultured into carbohydrate media for purposes of classification. Blood agar plates were also made which, when examined after twenty-four and again after forty-eight hours, supplied the first basis of classification of the streptococci into the two main groups, haemolytic and non-haemolytic. At the same time notes of the size and morphology of the colonies were made as a control of the other basis of classification.

The classification of streptococci cannot at present be regarded as satisfactory, and since in this investigation some simple basis appeared desirable it was decided to follow Holman's method<sup>1</sup>—splitting up the two main groups of haemolytic and non-haemolytic streptococci by means of the fermentative action of the isolated bacteria on three carbohydrates—lactose, mannite, and salicin. The basis of the medium was equal parts of tryptic broth and 1 per cent. peptone water. Tryptic broth was used, as better growth was secured by its presence than when peptone water was alone employed. It was not used exclusively owing to the possible action of streptococci on the glycerin which is present in it in small amount. It is doubtful if this precaution is really essential, as, in many controls made, no evidence of such action in sufficient amount to introduce any fallacy was observed; 1 per cent. of the carbohydrate was added and also 1 per cent. of Andrade's indicator. The tubes containing this medium were sterilized by the fractional method, and, after steaming, were enriched by the addition of 20 per cent. of sterile hydrocele fluid. They were always incubated for forty-eight hours before use to determine if any had become contaminated. After the three tubes were inoculated with each strain isolated, they were incubated and examined daily for five days. Usually the reactions were sharp and clearly read after twenty-four or, at most, forty-eight hours. Only very rarely were subsequent changes noted.

It is not contended that Holman's classification is perfect. Probably the number of types thus found is too small, but this appears to be preferable to a classification based on fermentative action on a large number of carbohydrates, which results in a multiplication of types. In all cases the morphology of the cocci and types of growth were compared with the results of carbohydrate fermentation, and only in a very few cases was any possible discrepancy observed.

## Results.

In all, 158 swabs were examined, and streptococci were found to be present in 101. In 3 cases two types of streptococci were found in the one swab. It is probable that if the number of colonies picked had been increased this would have occurred more frequently. In 13 cases streptococci were seen in the original broth culture, but were not typed. The reason, in 5 cases, was that it was impossible to isolate them owing to the presence of other organisms (*B. proteus*, etc.), while eight accidents in the laboratory (breaking of plates or tubes, too hasty discarding of plates, etc.) were responsible for the other omissions to type the organisms.

\*A paper preliminary to a discussion on puerperal sepsis at the British Congress of Obstetrics and Gynaecology, London, April 22nd.

An analysis of the results must now be attempted. For this purpose "probables," as explained above, are treated as if the organism had been correctly typed. The error so introduced, if any, is small.

TABLE I.—Gross Results Obtained.

Number of patients ...	50
Number of swabs ...	158
Streptococci absent ...	57
Streptococci present ...	101
Streptococci found ...	104
<i>Strep. faecalis</i> ...	43
<i>Strep. mitis</i> ...	42
<i>Strep. equinus</i> ...	10
<i>Strep. salivarius</i> ...	7
<i>Strep. equi</i> ...	1
<i>Strep. infrequens</i> ...	1

Of these streptococci only two, *Strep. equi* and *Strep. infrequens*, were haemolytic. *Strep. equi* was only moderately haemolytic, while *Strep. infrequens* was very actively so. The rarity of the haemolytic streptococci and the fact that neither of those found was identical with the *Strep. pyogenes*, the commonest cause of puerperal sepsis, tend to confirm our preconceived opinion that this organism is usually, if not always, introduced into the vagina from without in those cases in which puerperal sepsis from this cause appears, and that it is incapable of existing there as a saprophyte which becomes pathogenic on reaching the damaged uterine tissues. It must not, however, be forgotten that we only examined fifty cases, and that further material might cause us to change our opinion on this point.

All the other streptococci isolated were of the non-haemolytic or viridans type. The most numerous were the *Strep. faecalis* and the *Strep. mitis*, which were about equal in numbers, *Strep. equinus* and *Strep. salivarius* being less frequently found.

TABLE II.—Showing the Occurrence of the Various Organisms in the Vagina Before Delivery and in the Vagina and Uterus After Delivery.

	Before Delivery.		After Delivery.	
	Vagina.	Uterus.	Vagina.	Uterus.
Number of swabs ...	58	50	50	50
Streptococci absent ...	26	8	23	23
Streptococci present ...	32	42	27	27
<i>Strep. faecalis</i> ...	16	16	10	10
<i>Strep. mitis</i> ...	10	20	13	13
<i>Strep. equinus</i> ...	5	3	2	2
<i>Strep. salivarius</i> ...	3	2	2	2
<i>Strep. equi</i> ...	—	1	—	—
<i>Strep. infrequens</i> ...	—	1	—	—

We may first contrast the bacterial condition of the vagina before and after delivery. The figures seem to show, beyond doubt, that streptococci are more frequently present after than before the birth of the infant. In only 4 of the 50 cases were streptococci absent at all examinations. In 3 streptococci were present in the vagina before delivery, but were not found subsequently, while in 15 they were absent before delivery, but were found in that situation after the birth of the infant. The flushing of the vagina by the waters had evidently no more than a transient effect, if any, which was outweighed by the more suitable environment in which the streptococci found themselves after delivery, owing probably to the food material supplied by the lochia.

From the uterus itself we get our most surprising result. In 27 out of the 50 cases, streptococci were present in the swabs taken from the interior of the uterus with great care during the puerperium. It would appear that invasion of the uterus by vaginal streptococci does occur after delivery, but every invasion does not, of necessity, mean an infection. In four of our cases morbidity was shown by the temperature of the patient. One of these can be eliminated owing to the existence of pyelitis, leaving three for consideration. In two of these streptococci (*Strep. faecalis*) were isolated from the uterus, while the uterine swab from the other contained no streptococci. It is noteworthy that of the 27 instances of uterine invasion, the same organism was present in the uterus as in the vagina in 25; in 1 different

organisms were present, and in 1 streptococci were found in the uterus but not in the vagina.

The constancy of the vaginal and uterine flora at the three or more examinations made is worthy of some remark. Out of the 50 cases, in only 4 were all examinations for streptococci negative. In 37, including one case where a double invasion was found, either the same streptococcus or none was found at all examinations. In 9 there was a change of type. It is probable that a more extensive sampling of colonies would have revealed double invasions in many of these cases.

We do not wish to obscure by further analyses of our results what we consider our most important finding—namely, uterine invasions by streptococci in 54 per cent. of cases. While we were satisfied that our technique was good, we felt that we must face one obvious and fair criticism. To pass a swab into the uterus it is necessary to pass through the cervix in intimate contact with the vagina, admittedly containing streptococci. This passage permits the possibility of the picking up, by the swab, of streptococci not actually in the uterus. That this criticism is sound would appear by considering the first 25 and the second 25 of our cases separately. In the first 25 cases 17 uterine invasions were recorded, and only 10 in the second. Two gynaecologists were engaged in the collection of swabs in the first half of the series, both of whom had to learn by experience the best technique. In the second half all the swabs were taken by one individual who had already mastered the technique.

In order to meet this criticism a further investigation, which was confined to the puerperal uterine, was undertaken. The technique, which was as follows, was entirely carried out personally by one of us (G. F.G.). The patients were placed in a gynaecological chair, a posterior speculum was gradually passed into the posterior fornix, and the vagina wiped quite clear of lochia. The anterior lip of the cervix was then held and the cervical canal wiped clear. A 3/8 in. glass tube which had about 1 in. of cotton plug at one end and overlapping the edges of the tube, was prepared by boiling, and was then passed direct from the sterilizer for at least 2 in. into the uterine cavity. The culture swab was then passed up the glass tube and dislodged the cotton plug as it entered the uterine cavity. In all cases a flow of lochia came from the uterus into the glass tube, and in most cases flowed freely through the tube. The culture swab was then withdrawn and restored to its protecting test tube. It was thought that it would be helpful to attempt a numerical estimation of any streptococci found in these swabs, and therefore each swab, on receipt, was thoroughly washed in 5 c.c.m. of glucose hydrococo broth. Of this 0.5 c.c.m. was transferred to a second tube of the same medium and 0.1 c.c.m. to a third. A positive finding in the third tube indicated at least 50 streptococci in the swab, in the second 10, and in the first 1. The methods used for the isolation and typing of the streptococci was similar to that previously stated. In this series 25 patients were examined, on either the fifth or sixth day after delivery.

TABLE III.—Swabs from Puerperal Uterus.

Patient.	Streptococci found.	No. in Swab.
18 patients ...	None	—
A. J. ...	<i>Strep. mitis</i>	10
A. M. ...	<i>Strep. mitis</i>	1
M. McL. ...	<i>Strep. faecalis</i>	50
C. D. ...	<i>Strep. mitis</i>	1
M. P. ...	<i>Strep. faecalis</i>	50
C. H. ...	<i>Strep. faecalis</i>	50
M. K. ...	<i>Strep. non-haemolyticus</i>	10

Streptococci were therefore found in 28 per cent. of the uteri, as contrasted with 54 per cent. in the first series. This would seem to point to faulty technique in the earlier investigation, but, even if this be allowed, 28 per cent. of positive results is still very considerable. The very sceptical may hesitate to accept a single streptococcus (more probably a single chain of streptococci) as significant, but even if these are discarded there remain 20 per cent. of puerperal uteri invaded by streptococci of the viridans type in women exhibiting no sign of morbidity as determinable by temperature, pulse, or local condition.

## SUMMARY.

1. Streptococci were found in the vagina before and after delivery in 69 per cent. of the cases examined. They may therefore be regarded as among the normal flora of the part.

2. Haemolytic streptococci were only found twice in the examination of 108 vaginal swabs. *Strep. pyogenes* was never found.

3. The predominant non-haemolytic streptococci of the vagina were *Strep. faecalis* and *Strep. mitis*.

4. Non-haemolytic streptococci were present in the post-partum uterus in at least 20 per cent. of the cases examined.

We hesitate to draw any conclusions from our findings, but we suggest the following without wishing to dogmatize.

1. The commonest form of puerperal sepsis, that caused by haemolytic streptococci (and particularly *Strep. pyogenes*), is due to exogenous infection.

2. Non-haemolytic streptococci do occasionally cause puerperal sepsis. These organisms are present in the vagina of the majority of parturient women and are found fairly frequently in the uterus post partum. They are normal body saprophytes, but are opportunists as regards pathogenicity. (The *Strep. faecalis* may give rise to suppurative in wounds, and the *Strep. mitis* to septicaemia and subacute endocarditis.) Puerperal sepsis due to non-haemolytic streptococci is an endogenous infection. The cause is the streptococci of the vagina plus some unknown factor, which may be a local or general lowering of the patient's resistance or a rapidly enhanced virulence of the organism.

## BLOOD COAGULATION TIME IN THE INSANE.

BY

LIEUT.-COLONEL J. R. FORREST, R.A.M.C.(RET.),  
TICEHURST.

WHEN discussing with my friend Dr. F. E. Taylor the occurrence of haematoma auris in insane persons, he mentioned that it had been found that in cases of spontaneous haemorrhage into the vitreous the coagulation of the patient's blood had been delayed, and suggested that haematoma auris might be due to the same cause. It was Dr. Taylor's suggestion that induced me to make the investigation here recorded.

I found that the blood coagulation time was markedly prolonged in cases of haematoma auris, and I then deemed it advisable to test the blood of cases of insanity in general. The only reference I can discover in the literature to the blood coagulation time of insane persons is a paper by E. J. Larsen and H. Lind, who in 1920 recorded a series of 50 insane patients. They found that in all these patients the time was within normal range. I have not been able to see the original paper and do not know what method they used.

I have not succeeded in finding any reference to the matter in any of the textbooks or other works to which I have been able to refer. The subject of blood coagulation time, but without reference to insane subjects, has occupied the attention of many observers.

The method of measuring blood coagulation time adopted by different observers not only varies extremely, but there is no uniformity in the end-reaction which is sought. Thus, E. H. Lepper,<sup>1</sup> adopting the method of Dale and Laidlaw, takes the onset of coagulation as the point to be determined. This method is obviously objectionable as coagulation would be hastened by the agitation employed.

J. Addis<sup>2</sup> views under the microscope the edge of a drop of blood suspended in oil and acted on by a current of oil streaming against the edge of the drop. When a continuous smooth flow of the corpuscles ceases he concludes that coagulation has occurred in the drop. The apparatus used is not simple, and is open to the objection that contact with oil hinders or prevents coagulation.

The method of Sir Almoth Wright<sup>3</sup> is the simplest and most easily applicable. I adopted his method in a modified form in my experiments. I used capillary glass tubes 1 mm. in diameter and 6 cm. long; 2 cm. of the tube were filled with finger blood, the blood aspirated into the middle of the tube, and one end sealed in the flame. The unsealed ends

are then fixed in plasticine, and nipple, glass tubing, and plasticine are floated in a beaker of water kept at 37° C. A Hagedorn straight needle was used for pricking the finger, momentarily congested by a tape, and it is easy to fill simultaneously the four tubes used for each experiment by holding the tubes fan-shape between finger and thumb and inserting the approximated ends in the drop of blood.

I examined 117 cases, all being free from organic disease. In addition I examined 12 cases of normal sane persons. The average coagulation time in the 117 cases was 4.69 minutes. The average time in 12 normal sane persons was 3.75 minutes. This corresponds closely with the time given by other observers. J. H. Drysdale<sup>4</sup> says that normal coagulation time at temperature of body is about three or four minutes. E. R. Stitt<sup>5</sup> says that by Sabrazès's method finger blood coagulates in three to four minutes at room temperature.

Of the whole 117 cases, 63 gave coagulation times over the normal in sane patients. Of 10 cases of haematoma auris, 7 gave coagulation times above the normal. While these were the general results, it was noted that in 19 cases the time was six minutes, and 11 of these cases were mania. On the other hand, 14 cases gave a time under four minutes, and 10 of these were cases of dementia.

For some reason or another cases of haematoma auris are now very rare among the insane. In the private asylum where I am employed there are only 2 cases (recent), and at the East Sussex County Mental Hospital at Hellingly, with 1,350 patients, there were only 8 cases, and these were all old ones.

Tabulating the results we find—giving coagulation time over the normal: haematoma auris cases, 70 per cent.; insane cases, excluding haematoma, 52.3 per cent.; sane cases, 16.6 per cent. Coagulation time tends to decrease with increase of age of the patient.

## Conclusions.

1. The proportion of insane patients showing an abnormal condition of the blood is sufficiently large to indicate a line of treatment.

2. The prolonged coagulation time may well account for malnutrition of the brain tissue, and for the cerebral haemorrhages which so often occur in the insane.

3. The method of determining the coagulation time, as I have described it, is so simple that it can be easily done at the bedside.

4. Further investigation is needed to ascertain the factor or factors which prolong the coagulation time.

Is delayed coagulation in insanics due to decalcification, or to deficiency of prothrombin, or to deficiency of thrombokinase, which activates prothrombin, or which, according to Howell, is of lipid nature and neutralizes antithrombin?

It is probably not due to toxic substances produced by infective agents, as these would liberate a certain amount of nucleo-protein in the blood, and so produce coagulation.<sup>7</sup>

Halliburton<sup>8</sup> says that if we reject the thrombin theory with all its superstructures we accept a physical and not a chemical change as the cause of coagulation.

Sir A. E. Wright<sup>9</sup> points out that diminished coagulability of the blood is of very great practical importance, because it interferes with haemostasis, and also because it conduces to serious haemorrhage (in other words, to increased transudation).

It is to be noted that the observed blood coagulation time varies according to conditions of observation, temperature, etc., and the relative time between sane and insane is the important point. All my observations were made under exactly the same conditions. The absolute time will vary according to the method of observation.

My thanks are due to Dr. Taylor for the suggestion and much kindly advice, and to Dr. J. N. Greene Nolan of the East Sussex County Mental Hospital, Hellingly, where most of the work was done by kind permission of the medical superintendent. The rest of the work was done at Ticehurst House, Sussex, and I have to thank Dr. Colin McDowall for the facilities he gave me.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### TRACHEOTOMY TUBE WORN FOR OVER SEVENTY YEARS.\*

So far as my reading and experience go, the case reported in the JOURNAL of April 18th by Sir Robert Woods is the "record." In the JOURNAL for 1912 (April 6th, p. 816) Mr. W. A. Berridge records the wearing of a tracheotomy tube for over fifty years by a patient who died of senile decay at the age of 81. But in the case of Sir Robert Woods a patient of 81 has worn a tube for seventy years, and it is noted that "she never had bronchitis." These and many similar cases show that a disposition to bronchitis and other respiratory troubles is not a necessary sequel of the permanent wearing of a tracheotomy tube. Many such patients ("cannulars," as they call them in France) enjoy excellent health, earn their living by manual or other labour, play games and dance, and the females bear children after normal accouchements. If stenosis of the larynx is not complete, and the vocal cords, or even one of them, still functions, speaking can be carried on without blocking the tube, if the latter is fitted with a hinged valve. Of course, the operation must have been well carried out and the tube should fit properly. If the opening is made as low as possible in the neck—both for the sake of appearance and for scientific reasons—the tube is easily concealed behind a collar or a veil, and there is no social disability connected with it.

Such satisfactory records should make us pause, in certain cases, before embarking on difficult, tedious, and often unsatisfactory measures for dilating a stenosed larynx.

London, W.1.

STCLAIR THOMSON.

#### ACUTE CHOLECYSTITIS AT THE AGE OF THREE.

THREE years must be a very early age for the occurrence of acute cholecystitis, and this case is therefore thought to be worthy of record.

The child, a girl, was admitted on January 25th, 1925, with acute abdominal pain and vomiting. There was a previous history of eighteen months of vague abdominal pains, but never severe. She had never been jaundiced. At 10.30 p.m. on January 22nd she was awakened by vomiting, and severe pain in the abdomen. On the following day she was much better, and the parents thought she had recovered. The bowels were opened twice, and the stools were of normal colour. On January 24th, at 8.30 p.m., vomiting and abdominal pain again occurred, and continued all night. The bowels did not act. On January 25th the child was said to have been exhausted and was brought to hospital at 7 p.m.

When admitted she looked ill; the face was flushed, the temperature was 100°, the pulse 128, and the respirations 36. She was not jaundiced. The abdomen was distended, moving poorly on respiration. The point of maximum pain was at a spot 1½ in. to the right of the umbilicus and on a level with it. The whole abdomen was rigid, but especially in the right upper quadrant. No tumour or enlargement of the liver could be detected. Rectal examination revealed nothing abnormal. No abnormal urinary constituents were found now or later.

**Operation.**—Mr. J. E. H. Roberts, on January 25th at 11 p.m., examined the abdomen under an anaesthetic and felt a rounded tumour the size of a golf ball under the right costal margin; it was tense and fairly freely mobile. A right paramedian incision was made at the level of the umbilicus. A right paramedian incision was present in the peritoneal cavity. The gall bladder presented at the wound, and was greatly distended (5 in. by 1½ in.). The surface was smooth, shiny, and of a mottled purple colour. About 20 c.cm. of a transparent fluid, grass-green, and of the consistency of bile, was removed by a needle. Careful palpation failed to detect any calculi in any of the biliary passages. The gall bladder was then opened. The mucous membrane was very injected and bled freely. No stone was found with a spoon. A small rubber drainage tube

was sewn into the gall bladder, which was dropped back into the abdominal cavity. The remainder of the wound was then closed.

**Pathological Examination.**—The fluid from the peritoneal cavity on culture yielded *Staphylococcus aureus* and *albus* in the proportion of 1 to 10. The fluid from the gall bladder was acid and contained bile; it was sterile on culture, and no cells or organisms were present in it. Section of a portion of the gall-bladder wall showed it to be in a state of acute inflammation.

Except for some bronchitis and a little suppuration in the wound the child made an uninterrupted recovery, and was discharged quite well on March 3rd.

I am indebted to Mr. J. E. H. Roberts, who performed the operation, and to Mr. L. Batho Rawling, who afterwards had charge of the case, for permission to publish these notes.

JAMES R. HAMERTON, M.B., B.S.Lond., M.R.C.S.,  
House-Surgeon, St. Bartholomew's Hospital, London.

#### TORSION OF FALLOPIAN TUBES.

In recent numbers of the BRITISH MEDICAL JOURNAL there have been several references to this condition, which is apparently a definite clinical entity simulating acute appendicitis and affecting normal tubes. The cases recorded occurred during or within a few days of menstruation, and were characterized by abdominal pain and tenderness, rigidity of the lower fibres of the recti, and vomiting.

Reference to some recent textbooks of gynaecology has failed to reveal any mention of the condition, which, however, giving rise as it does to signs of an acute intra-abdominal catastrophe, might well be included in the differential diagnosis of such conditions as appendicitis, salpingitis, or ruptured ectopic gestation.

The following case, for permission to record which I am indebted to Dr. J. T. Bailey, exemplifies the condition.

A girl of 16 was admitted to hospital on August 1st, 1924, suffering from acute pain in the lower abdomen and vomiting. The attack had commenced the day before. She had not been constipated previously and was menstruating at the time. The lower fibres of both recti were rigid, particularly those of the muscle of the right side. There was tenderness in the right iliac fossa.

Laparotomy was performed, splitting the lower fibres of the right rectus. The ampullary part of the right Fallopian tube was black, swollen, and twisted on its mesosalpinx. The left tube, which had also undergone torsion but to a less extent, was congested, but not black, and on this side the twist was undone and the tube left *in situ*. The right tube was amputated and appendicectomy performed. Convalescence was uneventful.

A section of the right tube showed "a dense haemorrhage in which the remains of the wall of the tube could be seen." Dr. E. W. Bowell, assistant director of the Clinical Research Association, to whom I am indebted for the pathological report, commenting on this specimen, stated that several specimens very like it had been sent to him for examination. The specimens were mostly from young girls who had recently begun to menstruate. One was from a girl of 14, who was athletic, and it was suggested that exercise was a factor in her case.

In reviewing the records of cases of torsion of Fallopian tubes the outstanding feature is the absence of any external cause of torsion, such as adhesions, herniae, or the presence of tumours. Factors in the etiology would appear to be:

1. **Menstruation.**—The cases recorded have occurred during or in relation to menstruation. Several have occurred in association with the onset of menstruation at puberty, but P. R. Michaël has reported a case in a woman of 47 in whom, however, a normal menstrual period commenced three days after operation (*Epitome*, March 14th, 1925, para. 287).

2. **An abnormally long and free mesosalpinx.**

3. **Some muscular effort.**—In one or two instances attacks appear to have been precipitated by some strenuous exertion.

Torsion of otherwise normal Fallopian tubes is rare, but sufficiently common to merit attention and to be borne in mind when considering the differential diagnosis of acute intra-abdominal conditions. It most closely resembles appendicitis.

The Infirmary, Stockport. LAMBERT ROGERS, F.R.C.S.Ed.

\* A Sir Stclair Thomson notes, and another correspondent has written to a similar effect on this point, "over sixty years" in the title of Sir Robert Woods's memorandum was an understatement. The lady seems in fact to have worn the tube for seventy years.

## Congress of Obstetrics and Gynaecology.

THE fifth British Congress of Obstetrics and Gynaecology is being held this week in London at the house of the Royal Society of Medicine under the presidency of Dr. H. Russell Andrews. The constituent societies are the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, the Edinburgh Obstetrical Society, the North of England Obstetrical and Gynaecological Society, the Midland Obstetrical and Gynaecological Society, the Section of Obstetrics of the Royal Academy of Medicine in Ireland, and the Ulster Medical Society. The official guests of the Congress are Professor J. Whitridge Williams of Baltimore and Professor W. W. Chipman of Montreal. The proceedings opened on the morning of Wednesday, April 22nd, with the President of the Congress in the chair, when reports-in-chief on the "Prognosis and treatment of puerperal sepsis" were presented by a London Committee and a North of England Committee, as recorded below. These reports were followed by communications by Sir Ewen J. Maclean on puerperal sepsis in Wales (printed in full at page 770 this week); by Dr. Gibson FitzGibbon and Professor J. W. Bigger of Dublin (see pp. 773 and 775); and by Dr. L. P. Lockhart of Manchester on bacteriological examinations during pregnancy. Dr. Lockhart's paper comprised an abstract of a report of an investigation, which appears in full in the current issue of the *Journal of Obstetrics and Gynaecology*. The afternoon of April 22nd was devoted to a discussion on puerperal sepsis, of which we hope to publish a report in our next issue, together with an account of the later proceedings of the Congress.

### PUERPERAL SEPSIS.

#### LONDON COMMITTEE'S REPORT.

The following report on puerperal sepsis, compiled by a committee appointed by the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, is signed by Dr. H. Russell Andrews (chairman), Sir Ewen J. Maclean, and Mr. Aleck Bourne. In preparing this report, and that of the North of England Committee, for publication here, some abridgement has been necessary.

#### INTRODUCTION.

We were asked to prepare a report, on as large a number of cases of puerperal sepsis as possible, which would serve as a basis of discussion. We sent out a large number of forms with numerous headings under which details of cases of puerperal sepsis were to be entered, and, on the suggestion of the North of England Committee, laid down rules as to what cases were to be considered suitable to be recorded, as follows:

"Reference is made only to cases arising within the first twenty-one days of the puerperium from infections of the placental site or from lacerations of the genital canal. Positive indications of blood infections should be taken to be one or more of the following: (1) isolation of the organism, by blood culture; (2) prolonged pyrexia; (3) repeated rigors; (4) pyaemia, including septic pneumonia; (5) death from puerperal fever irrespective of *ante-mortem* symptoms."

The response from some parts of the country was most encouraging to the continuance of this form of collective investigation, while the response from other parts was meagre in the extreme. Altogether details of 408 cases were sent in. A careful process of selection reduced the numbers to 247. Some had to be excluded as not showing sufficient evidence of blood infection, others because the notes were not sufficiently full. In a great many of the cases some of the details asked for were missing. This was inevitable, as in few, if any, institutions are septic puerperal cases allotted to students for routine history-taking and note-taking, and the officers in charge of these cases have usually more urgent duties than that of taking comprehensive notes.

The report is based on analyses of these 247 cases, in which recovery took place in 160, and death in 87. (We do not wish it to be thought for a moment that we consider that these figures prove that 64 per cent. of cases of puerperal sepsis recover and 36 per cent. die!) The original arrangement was that the North of England report, which was to be printed separately, should be blended with this report, but it was decided later that if this blending was to be carried out it would have to be done after the meeting of the Congress, as it might be necessary to spend a good deal of time over it in case the selection of cases had been made more drastically by one committee than by the other.

#### ETIOLOGY.

A statement which is frequently heard at consultations is that puerperal sepsis occurs in cases in which the labour has been left to nature, the medical attendant possibly not even making a vaginal examination, and that cases in which a great deal has to be done seldom "go wrong." Our figures do not at all bear out the latter part of this view, but show that in 25 per cent. of cases there is no obvious etiological factor present.

In 160 cases in which recovery took place there were 42, or 26 per cent., and in 87 fatal cases there were 19, or 22 per cent., in which the labour could be said to be normal and spontaneous, with no special risk of infection from lacerations, cervical or vaginal discharge, or from other causes. This is the group which presents the greatest problem.

**Exhaustion.**—In the cases in which recovery took place the labour was said to be prolonged in 16 cases. In one of these cases it apparently finished spontaneously. The mode of delivery in the other cases was: forceps, 3; forceps, craniotomy, tear, 1; forceps, manual removal of placenta, 1; pubiotomy, sloughing of vagina, 1; breech, 1; breech, laceration, 1; breech, blunt hook, very severe laceration, 1; extensive laceration, 1; craniotomy, 5. In 65 fatal cases excessive length of the labour is noted in 7 cases; protracted labour, pubiotomy, forceps, 1; protracted labour, forceps, episiotomy, perineal tear, 1; protracted labour, putrid liquor amnii, episiotomy, forceps tear, 1; long impaction of head, craniotomy, 1; long impaction of shoulder, version, 1; prolonged labour, six days, 1; prolonged breech extraction, 1. Exhaustion was probably a factor in many other cases—for example, "obstructed labour, forceps"; "forceps applied four times, tear"; "forceps, cephalotripsy, bladder injured, terrible tearing"; "many attempts at delivery by the forceps and version"; "impacted shoulder, internal version, small tear of anterior wall of uterus," etc. It may be taken that in any forcible method of delivery which resulted in extensive laceration exhaustion may have been present.

**Laceration, Bruising, and Manipulation.**—In 160 cases in which recovery took place there were 42 cases of normal, spontaneous labour with no tear, with no retention of a portion of placenta, no gonococcal or cervical discharge, and no direct or indirect contact with septic cases—that is, 26 per cent. in which there was no suggestion of a source of infection, except that in some cases the recorder blamed the midwife or the doctor, on what evidence we do not know. [The Committee's tabular analysis of the abnormalities or interferences in the other 118 cases is omitted here.] Thus there was some extra risk of infection in no less than 74 per cent. of the cases in which recovery took place, and in 21 cases or 13 per cent. of the whole number the placenta was removed by hand. In 37 cases at least there was some laceration. These figures may be analysed from another point of view—namely, "What amount of interference had there been in the labours of patients who became infected and recovered?" Cases in which lacerations occurring in spontaneous labour were sutured, and in which a portion of retained placenta was removed, are not included under the term "interference in labour." (We do not suggest that the interference was unnecessary in the circumstances and are making no criticism, but are simply recording facts from

the figures given above.) Out of 160 labours of patients who recovered there was interference in 78, or 49 per cent. The forceps was used, frequently with resulting laceration, sometimes followed by craniotomy or version, in 44 cases. Version was performed in 4 cases, craniotomy in 6 cases, Caesarean section in 2 cases, and pubiotomy in 2 cases. Labour was induced in 6 cases, assistance was given with the breech in advance in 5 cases. In one case the patient tried to bring on labour herself by intravaginal manipulations. In 21 cases the placenta was removed manually. Out of 87 fatal cases, labour was spontaneous and normal in 19; spontaneous with laceration of the perineum, vagina, or cervix in 9; spontaneous with retention of a portion of placenta in 5; spontaneous with bleeding in 2; spontaneous with "contact" in 5—that is, spontaneous in 40 or 46 per cent. (One of the "spontaneous and normal" labours was followed by gangrene of the vagina and uterus.) In the remaining 47 cases, or 54 per cent., labour was abnormal. [The details of abnormal labour in the 87 fatal cases are omitted here.] In 47 fatal cases out of 87 there was interference in the labour—that is, in 54 per cent. In 57 fatal cases out of 87 there was some special risk of infection (retention of a portion of placenta after spontaneous labour being included and tearing in spontaneous labour being excluded)—that is, in 65 per cent. of cases. An analysis of the 160 non-fatal and 87 fatal cases taken together gives the following figures:

Out of 247 cases labour was spontaneous in 122, or 49.4 per cent.; there was interference in labour in 125, or 50.6 per cent.

Excluding laceration in spontaneous labour there was some special risk of infection in 154 cases, or 63 per cent.

Including laceration in spontaneous labour there was some special risk of infection in 186 cases, or 75 per cent.

**Manual Removal of the Placenta.**—It is difficult, by statistics, to show with much accuracy the frequency with which manual removal of the placenta was followed by septic infection, because in many cases the relative importance of this factor was complicated by the performance of other manipulations or operations. The placenta was removed manually in 34 cases—21 non-fatal and 13 fatal. Among the non-fatal cases the placenta was removed manually in 16 cases after spontaneous labour. In one of these the cervix had been torn, in one there was a sloughing perineal tear, in one case there was albuminuria, and in one case there was "latent gonorrhoea." In several cases there had been post-partum haemorrhage of varying degree and in some the placenta was not removed until several hours after the birth of the child. . . .

Among the fatal cases the placenta was removed manually without other operation, in seven cases, in one of which post-partum haemorrhage is recorded. One of the spontaneous cases was followed by gangrene of the vaginal wall and uterus.

**"Contact" Cases.**—Direct transference of infection from one patient to another, which formerly bulked so largely as the cause of puerperal fever, was directly observed and traced in 15 cases, and in one other case the evidence was doubtful. Contagion, therefore, accounts for an incidence of 6 per cent. in the whole series. The first series of contacts is of sufficient interest to report in full:

#### The Infecting Case.

Mrs. M. O'C. came into labour with pyrexia already developed, with a pleural effusion and superficial thrombosis of arms and legs. There were three rigors. Labour was normal and no examination was made. This patient recovered.

#### The Infected Cases.

1. Normal labour, no streptococcus found in the blood—recovery.
2. Normal labour, one rigor, no streptococcus found in the blood—recovery.
3. Indirect contact with Mrs. M. O'C. for twenty-four hours. Normal labour. Haemolytic streptococcus, no rigors, general peritonitis—died seventh day.
4. Indirect contact. Caesarean section. Blood culture yielded haemolytic streptococcus. No rigors. Died on the eighty-fourth day.
5. Normal labour. Haemolytic streptococcus. No rigors, general peritonitis—died on the thirtieth day of puerperium.
6. Easy normal labour, simple laceration of perineum, blood negative, no rigors, general peritonitis—died eleventh day of puerperium.

The comment made by the obstetrician reporting this series is as follows:

"All the above developed close together, having been confined with Mrs. M. O'C., who had ante-partum pyrexia. Not strictly isolated, but no connexion between nurses examining the cases could be found, and no examination was at any time made on Mrs. M. O'C. But there was a certain amount of commo mixing during the actual labours of the six secondary cases, extending over periods of from twelve to twenty-four hours, after which these cases were removed to separate wards."

This series, with its enlightening commentary, serves to show how subtle may be the means of infection by contagion. The infecting woman was never examined vaginally, yet her mere presence within the radius of the ordinary traffic of the wards was sufficient to disseminate serious and fatal infection. [Details of the other series are omitted here.] In spite of the commonly accepted view that secondary cases are usually of fulminating severity, of the 15 cases of contact infection only 5 died, a mortality of 33 per cent., as compared with 36 per cent. for the whole series.

**Autogenous Infection.**—The important question of the frequency and danger of autogenous infection as a cause of puerperal sepsis cannot, unfortunately, be elucidated by this inquiry. Any opinions on the etiological possibilities of this form of infection must rest upon evidence specially collected *ad hoc*, and such evidence can only be obtained by detailed investigation of women before labour, coupled with observation of the puerperium afterwards. The data supplied to us in this series of cases give the occurrence of septic foci in the body as possible causes of puerperal sepsis in only 5 cases, in none of which was there any identification of the focal organism with the causative agent of the puerperal infection. It is possible, if not probable, that some of the cases recorded in this report as arising after prolonged and exhausting labour or haemorrhage may have developed puerperal fever by reason of the diminished resistance of the patient failing to hold in check organisms which had been long resident in her body. In spite of the absence of serious consideration of autogenous infection in this report, we wish, however, to suggest that some exact work to clear up this question is urgently needed, for until it is definitely known what proportion of cases can be ascribed to autogenous infection our ideas of the correct prophylaxis of puerperal sepsis cannot be complete. Of this series of 249 cases, 5 only were reported as being suspected of autogenous infection. They are as follows:—*Recovered*: Gonococci in the cervix and normal labour—3 cases; cervical discharge with precipitate labour, and no examination made—1 case. *Died*: Calculous pyelitis and induction—1 case. The urine of this patient contained a streptococcus which was later identified by sugar reactions with the organism recovered from the blood and uterine cavity.

**Haemorrhage in Labour.**—The generally accepted view that haemorrhage in labour plays a serious part in the etiology of puerperal sepsis directly by lowering resistance, and indirectly by involving the patient in manipulative treatment, is borne out by the results of this inquiry. Of the whole series, 20 patients are notified as having had haemorrhage, either before or after labour, to a pathological degree. [The analysis is omitted here.] Considering all cases of haemorrhage we find that of 20 cases 13 died, yielding a mortality of 65 per cent., while the incidence of haemorrhage as an etiological factor in the whole series stands at about 8 per cent.

**Albuminuria.**—The presence of albuminuria was noted in 14 cases, but in most of them there was no account of the amount of albumin or the coexistence of other signs of toxæmia, which, if recorded, might furnish evidence as to how far the albuminuria was a real factor in the etiology or merely an incident. It is perhaps worth while recalling that out of 80 fatal cases of eclampsia reported by the Committee on Obstetrics and Gynaecology of the Royal Society of Medicine, only one death was directly attributable to sepsis—namely, general peritonitis. [The analysis of the patients is omitted here.] It is clear on examining the fatal cases that 3 of the 5 were complicated by other factors (such as haemorrhage and trauma) which were in themselves not only liable to predispose to sepsis, but also

likely to lead to fatal issue. Of the patients who recovered, 6 out of 9 were notified as having albuminuria only—that is, without any other of the conditions which ordinarily predispose to sepsis. From the comparatively few cases at our disposal we may perhaps conclude, therefore, that albuminuria does not play a great part in the causation of puerperal sepsis by lowering resistance, and that where albuminuria is the only condition present the chances of recovery, other things being equal, are good.

**Exploration of the Uterus during the Puerperium, with or without Curetting.**—We had hoped that this investigation might give some definite information about the risk attached to exploration of the uterus in cases of puerperal pyrexia. Unfortunately, however, the notes are in most cases too meagre to be of much value from this point of view, as they do not state the nature of the exploration—that is, whether a retained portion of placenta was removed or not, and whether the uterus was curetted or not. Exploration of the uterus is recorded in 15 cases, of which 12 were fatal. [Details are omitted here.] These figures are small, but it is worthy of note that 80 per cent. of the cases in which the uterus was explored were fatal. The operation, so far from doing good, probably did harm in some of them. We were agreeably surprised to find that exploration had been carried out in such a small number, as we had learned to regard it as a very dangerous procedure. It is interesting to note that retention of a portion of placenta played such a small part in the etiology of the recorded cases.

**Induction of Labour.**—Among the 247 cases labour was induced in 9; 3 of the patients recovered and 6 died. The fatal cases were: (1) albuminuria, bongies, secondary post-partum haemorrhage; (2) albuminuria; (3) albuminuria, post-partum haemorrhage; (4) chorea; (5) Champetier de Ribes's bag, manual removal of the placenta; (6) auto-genous infection.

#### CLINICAL FEATURES.

The following table indicates the onset of pyrexia in 230 cases. It shows the day on which the pyrexia started in cases in which recovery took place and in which death occurred. (0=the day on which the labour finished.)

Day.	Recovered.	Died.	Day.	Recovered.	Died.
0	...	4	7th	...	5
1st	...	7	8th	...	5
2nd	...	25	9th	...	1
3rd	...	37	10th	...	7
4th	...	32	12th	...	3
5th	...	11	13th	...	1
6th	...	8	16th	...	0

It will be seen that in 25 per cent. the onset was on the third day; in 20 per cent. on the fourth day. In 83 per cent. the onset was in the first five days.

The next table shows the percentage of cases in which the onset occurred on each of the first seven days.

Day.	Recovered.	Died.	Day.	Recovered.	Died.
0	...	3	4th	...	22
1st	...	5	5th	...	8
2nd	...	17	6th	...	5
3rd	...	25			

It will be seen that, except on the day after delivery, there is very little difference between the percentages of non-fatal and fatal cases.

**Degree and Character of the Pyrexia.**—In 107 cases the pyrexia was said to be remittent; among these cases there were 73 recoveries and 34 deaths. In 61 cases the pyrexia was said to be persistent; among these cases there were 34 recoveries and 27 deaths. Reduced to percentages there were 68 per cent. of recoveries and 32 per cent. of deaths with remittent pyrexia; there were 56 per cent. of recoveries and 44 per cent. of deaths with persistent pyrexia. In 56 per cent. of the fatal cases there was a remittent type of pyrexia, and in 44 per cent. a persistent type. An analysis of the degree of pyrexia resulted in the finding that in cases in which recovery took place the average highest temperature was 103.3° F., and that in fatal cases 103.2° F. The degree of pyrexia is apparently of little

prognostic value. A study of charts would be much more likely to provide useful information than a mere record of the character of the pyrexia and of its highest point.

**Pulse Rate.**—With a pulse rate under 140 per minute the fatal cases were 29 out of 132, or 22 per cent. With a pulse rate of 140 or over the fatal cases were 52 out of 94, or 55 per cent.

With a pulse rate of 110 and under,	96% recovered,	4% died.
" " 120	79% "	21% "
" " 130	60% "	40% "
" " 140	58% "	42% "
" " 150	29% "	71% "
" " 160	17% "	83% "

The above figures are very striking, and suggest that the frequency of the pulse is of great importance from the point of view of prognosis.

**Rigors.**—In 205 cases there was a definite note as to presence or absence of rigors. In 118 of these cases (58 per cent.) the presence of rigors was noted; in 87 cases (42 per cent.) the absence of rigors was noted. Of the 118 cases with rigors 78, or 66 per cent., recovered, while 40, or 34 per cent., died. Of the 87 cases without rigors 52, or 60 per cent., recovered, while 35, or 40 per cent., died. The mortality in the cases with one rigor was 36 per cent.; in the cases with two rigors 13 per cent.; in the cases with frequent rigors 38 per cent.; in the cases with no rigors 40 per cent. Most, if not all, of the patients were being looked after by trained nurses. Where the patient or an inexperienced nurse might not consider that a rigor had occurred unless the bed had been shaken and the teeth had chattered, an experienced nurse would notice the altered appearance of the patient with a complaint of a feeling of chilliness, or of "cold water running down the spine," with perhaps only a slight degree of shivering, would take the temperature and find a temporary rise to 104° F., 105° F., or higher. We must take it that in the 87 cases in which "no rigors" was recorded rigors did not occur, though it is possible that in the records in which a dash was put in the column for rigors they may have occurred, but this element of doubt does not affect the fact that in 35 fatal cases there were no rigors. The presence or absence of rigors cannot be taken as an important prognostic sign. [Tables showing the day of puerperium and the day of pyrexial period on which the first rigor occurred are omitted here.] The first rigor occurred in 8 per cent. of the total cases on the first day after labour, in 17 per cent. on the second, in 27 per cent. on the third, and 9 per cent. on the fourth; in 8 per cent. of the non-fatal cases on the first day after labour, in 15 per cent. on the second, 13 per cent. on the third, and 9 per cent. on the fourth; in 7 per cent. of the fatal cases on the first day after labour, 23 per cent. on the second, 17 per cent. on the third, and 7 per cent. on the fourth. The only useful fact shown by the above is that in fatal cases the rigors tended to occur early in the puerperium. In 67 per cent. of the total cases the first rigor occurred on the first day of the pyrexial period; in 71 per cent. of the non-fatal cases the first rigor occurred on the first day of the pyrexial period; in 62 per cent. of the fatal cases the first rigor occurred on the first day of the pyrexial period.

**Sleep.**—Owing to a change in the headings we were not supplied with information as to the character of the patients' sleep after the first groups of forms had been returned, except that insomnia was noted. In 111 cases the character of the sleep is noted, good or fair in 72, bad, poor, or "insomnia" in 49. In cases in which the patient slept well the mortality was 19 per cent.; in cases in which the patient slept badly the mortality was 75 per cent. In 16 cases in which insomnia was noted the mortality was 81 per cent.

**Tongue.**—Dryness of the tongue, according to most of the reports, seems to be of grave prognostic significance, but in a few of the forms sent in most of the patients who recovered were said to have dry tongues. Probably the dryness of the tongue in these cases was noted only on admission, before the patients had come under the care of skilled nurses. Dry tongue was noted in 72 cases, of which 33, or 46 per cent., were fatal.

**Other Symptoms.**—Vomiting was noted in only 4 cases, all fatal. Diarrhoea was noted in 20 cases, in 17 of which, or 85 per cent., the patient died. Delirium was noted in 30 cases, in 26 of which, or 87 per cent., the patient died. General peritonitis was noted in 16 cases, 15 of which, or 94 per cent., were fatal. Pneumonia was noted in 11 cases, of which 8, or 73 per cent., were fatal. Mania was noted in 5 cases, of which 3 were fatal.

**Pyæmic Abscesses** were noted in 13 cases during life, 6 of which, or 46 per cent., were fatal. In 5 cases, all of which recovered, abscesses developed in the buttock, at the site of quinine injections. This bears out the teaching that the formation of a fixation abscess indicates a rising resistance, and is of good prognostic significance. In one hospital, where several hundred quinine injections have been given, no abscesses developed except in one case in which an injection of ergotin before admission was thought to be responsible.

#### RESULTS OF EXAMINATION OF THE BLOOD.

In 53 cases streptococci were found in the blood; in 4 *B. coli* was found in the blood; in 79 the blood was said to be sterile. It would probably be more correct, in some of these cases, to say that streptococci were not found than that the blood was sterile, since in some of the positive cases streptococci were not found on the first or second examination, but were found later. Of the 79 negative cases 16, or 20 per cent., died, and 63, or 80 per cent., recovered.

Of the 53 cases in which streptococci were found 35, or 66 per cent., died; 18, or 34 per cent., recovered. It will be seen that the mortality was more than three times as great when streptococci were found in the blood as when they were not found. [Detailed analyses of the 53 cases in which streptococci were found in the blood are omitted here.] Among these cases there were 20, or 38 per cent., in which there were no rigors. Sixteen of these cases were fatal and 4 non-fatal—that is, 80 per cent. of the "blood positive" cases without rigors were fatal and 20 per cent. non-fatal.

Of the 4 cases in which *B. coli* was found in the blood, 3 cases recovered, with one, two, and three rigors respectively; pulse 110, 140, 172. There was one spontaneous labour. In one case the vagina and lower uterine segment were packed to induce labour. In one case delivery was by forceps. One patient died—eight rigors, pulse 140, placenta prævia, bipolar version, manual removal of placenta, bronchopneumonia.

#### TREATMENT.

We had hoped to make some useful deductions on the subject of treatment, but have been unable to do so. There were over sixty different methods of treatment or combinations of different methods. In the first 31 cases analysed, in which the treatment consisted of "general medical treatment," there were 25 recoveries and 6 deaths, but it would be absurd to deduce from this that treatment of puerperal sepsis by general medical measures results in nearly 81 per cent. of cures!

In 33 cases treated by antistreptococcal serum and injections of quinine there were 28 recoveries and 5 deaths—a mortality of 15 per cent.—while 11 patients treated by intramuscular injections of quinine alone all recovered. Of 14 patients treated with antidiphtheritic serum only 1 died, while 3 patients treated by colloidal iodine and neosalvarsan all died. It should be stated that some of the cases mentioned above in which recovery took place were afterwards discarded as not being sufficiently severe to come into this report, but the labour which would be involved in getting out corrected figures did not seem to be worth while.

The various methods of treatment adopted, alone or usually in combination with one or more others, included general medical, postural, douching, antistreptococcal serum, vaccines (stock and autogenous), colloidal iodine, colloidal argentine, transfusion of blood, immunotransfusion, saline solution or sodium bicarbonate solution per rectum and intravenously, quinine intramuscularly and intra-

venously, phylacogen, antidiphtheritic serum, *B. coli* serum, eusol intravenously, irrigation of the uterine cavity with methyl violet and crystal green, and intravenous injections of mercuriol and mercury perchloride.

This long list suggests that the best method of treatment is still being sought. Would it be possible to parcel out various definite methods of treatment to selected hospitals so that results could be compared in a year's time, or are the conditions too diverse to be feasible?

#### DURATION OF LIFE IN FATAL CASES AFTER THE ONSET OF PYREXIA.

In 83 cases the average duration of life after the onset of pyrexia was eighteen days, but this average was unduly high by inclusion of a few cases which dragged on for weeks or months. The most fatal day was the eighth, on which 8 patients, or 10 per cent. of the total, died. On the fourth and fifth days together 14 patients, or 17 per cent., died.

Thirty-one patients, or 37 per cent., died in the first week. Seventeen patients, or 20 per cent., died in the second week—that is, 57 per cent. in the first two weeks.

Ten patients, or 12 per cent., died in the third week—that is, 69 per cent. in the first three weeks.

Ten patients, or 12 per cent., died in the fourth week—that is, 81 per cent. in the first four weeks.

Eight patients, or 10 per cent., died in the fifth week—that is, 91 per cent. in the first five weeks.

One patient died on the 48th day.

Three patients died between the 50th and 60th days.

One patient died between the 60th and 70th days.

One patient died between the 80th and 90th days.

One patient died on the 180th day.

(Some of these patients died of marasmus, the effect of adhesions due to intraperitoneal suppuration.)

Excluding these last seven cases, the average duration of life of the remaining 76 patients was fourteen days after the onset of pyrexia, and 63 per cent. of them died in the first two weeks.

#### POST-MORTEM FINDINGS.

The following is a summary of the *post-mortem* findings in 35 fatal cases, with the number of days of duration of life after onset of pyrexia.

General peritonitis, six cases, 4, 4, 7, 7, 9, and 17 days.  
Abdomen full of pus, no gross lesions of organs, 4 days.  
Free pus in abdomen, 35 days.  
Abdomen full of pus, 7 days.  
Multiple abscesses in kidney, 9 days.  
Double pyosalpinx, 56 days.  
Pneumonia, enlarged spleen with abscesses, 52 days.  
Nothing remarkable in pelvis, a little blood-stained free fluid, spleen enlarged and almost fluid, 11 days.  
Gangrene of vaginal wall and uterus, 10 days.  
Endometritis, septic spleen, general peritonitis, 2 days.  
Acute vegetative endocarditis, nil else, 66 days.  
Pericarditis, abscesses of kidney, endometritis, 14 days.  
Putrid endometritis, necrotic. Tubes infected. Peritoneum healthy, 3 days.  
Putrid endometritis, necrotic. Tubes infected. Peritoneum healthy, 3 days, no pyrexia.  
Abscesses in hand, shoulder, ankle, and eye, and multiple in uterus and parametrium, 25 days.  
Putrid endometrium, 2 days. Albumin.  
Nothing remarkable, 8 hours.  
Gangrene of uterus, necrotic pus in parametrium, double pyo-thorax, multiple abscesses in lung, 18 days.  
General peritonitis, infection from Fallopian tube, 4 days.  
Abdomen full of pus, right tube infected, right lung partly consolidated, 10 days.  
General peritonitis, no local lesion, 3 days.  
No peritonitis, uterus large and soft and pulpy, internal surface oozing pus, small tear anterior surface sealed by adhesions, internal version, impacted shoulder, 8 days.  
General peritonitis, cystitis, and parametritis, 4 days.  
Gas-forming organisms in uterus, liver, and large blood vessels.  
Purulent general peritonitis and parametritis, 4 days.  
Acute endocarditis, thrombosis of ovarian vein, 7 days.  
Uterus full of pus, multiple abscesses in uterine wall, septic embolism in lungs, 24 days.  
Anterior parametritis, uterus lined by septic granulation tissue, 27 days.  
Infected placental site, left veins, abscess left ovary, 7 days.  
Sloughing of genital tract and buttock, 7 days.

[The report concludes with a series of brief notes of some serious cases (nine in number) in which the patients recovered. These cases serve to illustrate (1) the old maxim, "never give up hope in a septic case," and (2) some of the diverse methods of treatment adopted.]

## SUMMARY OF PROGNOSIS.

To sum up, this analysis suggests that the following should be considered to be of grave significance:

1. Onset of pyrexia during labour or within twenty-four hours of its termination.
2. Extensive tissue damage in the labour, particularly tearing of vagina and cervix rather than of perineum only.
3. Presence of streptococci in the blood.
4. Persistently high pulse rate.
5. Insomnia.
6. Diarrhoea with or without general peritonitis.
7. General peritonitis, pneumonia, or delirium.

The following signs and symptoms are of good prognostic significance:

1. Absence of streptococci in the blood.
2. Moderately low pulse rate, about 120.
3. Freedom from insomnia and diarrhoea.

## NORTH OF ENGLAND COMMITTEE'S REPORT.

The report of a committee of the North of England Obstetrical and Gynaecological Society on puerperal blood infections was presented to the Congress on April 22nd. The Committee was appointed in January, 1924, and consisted of Professor W. Blair Bell (Chairman), Mr. John Chisholm, Dr. Daniel Dougal (Secretary), Mr. Carlton Oldfield, and Mr. Leyland Robinson.

## INTRODUCTION.

This report is based upon an analysis of 154 cases of puerperal septicaemia, selected in accordance with the qualifications laid down at the beginning of the investigation, and set forth on the special forms drawn up by the London Committee in conjunction with the Committee of the North of England Society. [The conditions are set out in the London Committee's report, at page 778.]

It will be apparent that only the most serious cases are taken into account, and in view of the high mortality rate in our series it is important that this should be fully understood at the outset.

The printed puerperal fever forms received from various sources have been carefully examined, and the information obtained has been analysed under the following headings: (1) Etiology; (2) Symptoms; (3) Pathology and Bacteriology—(a) pathological anatomy, (b) bacteriology; (4) Treatment—(a) intrauterine methods, (b) abdominal operations, (c) serological methods, (d) drugs, (e) other methods. The majority of the cases were treated in institutions, but a few came from private sources.

Nearly half of the cases—72 to be exact—were admitted to the Walton Institution of the West Derby Union, Liverpool, and the Committee wishes to record its appreciation of the work done by the medical officer, Dr. H. H. MacWilliam, in collecting so much valuable material and placing it at the disposal of the society.

## ETIOLOGY.

In considering the question of etiology, account must be taken of the patient's general health and surroundings, the efficiency of the antiseptic precautions employed by the doctor or midwife in attendance, the character of the labour, and the nature of any obstetric operation performed. It is impossible to express any opinion on the first two points, for the data available are too scanty, but in regard to the others a good deal of useful information has been obtained.

In over 46 per cent. of the cases labour was normal—there was no interference whatever, apart from vaginal examinations. The number of these examinations is not known, except in a few cases specially mentioned in the table. Forceps were used in 29.2 per cent. of the cases, and the placenta was removed manually in 15.6 per cent. The latter figure is important, and shows that the risk of septic infection following manual removal of the placenta has not been exaggerated. There is one instance of infection after packing of the vagina, but the case—one of placenta praevia—was further complicated by the fact that there was a gonorrhoeal vaginal discharge.

The source of infection has next to be considered, and

any conclusion which may be drawn is largely a matter of speculation. There are seven cases in which the patient had some infective condition prior to the onset of labour, and in these the infection may have been autogenous. In the majority of cases, however, it has to be assumed that the infection came from without, and was introduced during delivery. In five cases there is strong evidence to show that the nurse's hands were responsible—three were attended by the same nurse, one was attended by a nurse who had a bad reputation as regards asepsis and had two other deaths a short time previously, and in the remaining case the nurse was suffering from some feverish condition at the time she delivered the woman. Two cases were attended by a doctor suffering with a septic finger. The two cases in which the infection is supposed to have been conveyed from another patient are interesting. In one a patient in the next bed was found to be suffering with scarlatina; in the other, the woman's husband developed erysipelas of the face, and was transferred to a fever hospital. This misfortune so upset his wife that labour started prematurely, and the child was born before the arrival of either doctor or nurse. This patient developed septicaemia, in spite of the fact that everything was normal at the confinement and there was no vaginal examination.

One other point in connexion with etiology may be mentioned here, and that is the possibility of minor degrees of sepsis being converted into blood infections by intrauterine methods of treatment. If the first rigor be taken as an indication of the onset of blood infection, it is possible to examine 43 cases where sufficient data are available. In 13 cases the uterine treatment was carried out prior to the occurrence of the rigor, but in one of these the rigor which occurred was apparently due to the intrauterine method adopted for the administration of antistreptococcal serum. In four instances the rigor was definitely stated to have occurred immediately after the intrauterine treatment.

## ETIOLOGICAL FACTORS.

## Relation between Intrauterine Methods of Treatment for Sepsis and Onset of Septicaemia.

Serial No.	Day of Onset of Pyrexia.	Day of First Rigor.	Nature and Day of Intra-uterine Treatment.	Result.
1	5	5	Curetting, 12th day	Died.
5	7	7	Donche, 11th day	Died.
9	2	9	Exploration, 4th day	Died.
19	2	2	Donche, 5th day	Died.
12	2-3	6	Explored, 7th day	Died.
14	2	2	Nil	Died.
15	2	2	Donche, 2nd day	Died.
16	3	3	Explored, 10th day	Died.
23	5?	5	Washed out, 5th day	Died.
24	1	9	Washed out, 2nd day	Died.
25	9	9	Donche, 31st day	Died.
27	3	5	Explored, 6th day	Died.
28	1	1	Explored, 8th day	Recovered.
29	3	3	Explored, 4th day	Died.
30	3	(serum)	Donche, 3rd day	Died.
32	8?	8	Clots removed, 8th day	Died.
35	3	3	Nil	Died.
38	3	3	Explored, 6th day	Died.
41	4	4	Nil	Died.
42	3	3	Explored, 7th day	Died.
43	4	4	Explored, 6th day	Died.
44	1?	6	Explored, 4th day	Died.
46	4	7	Nil	Died.
47	10?	10	Donche, 18th day	Died.
48	2?	10	Nil	Died.
49	4	13	Donche, 9th day	Died.
50	8?	8	Donche, 12th day	Died.
52	4	4	Donche, 6th day	Died.
55	2-3	4	Curetting, 6th day	Recovered.
57	5?	5	Curetting, 10th day	Recovered.
59	3	3	Nil	Recovered.
60	3	3	Donche, 5th day, explored 6th day	Recovered.
64	4	14	Curetting, 4th day	Recovered.
65	8?	10	Curetting, 10th day	Died.
107	4	4	Donche, 7th day	Died.
117	18?	18	Curetting, 19th day	Died.
123	17	18	Removal of R.P.C., 17th day	Died.
130	9	13	Removal of R.P.C., 13th day	Died.
132	4	2	Glycerin injected into uterus, 9th day	Died.
138	1	1	Curetting and douching, 1st day	Died.
143	8	11	Removal of R.P.C., 9th day	Died.
150	3	5	Uterus douched, swabbed, and packed at delivery	Recovered.

NOTE.—An asterisk has been placed opposite those cases in which the first rigor occurred after intrauterine treatment.

Other etiological factors in this series of cases, which are tabulated in the Committee's report, are printed here in abstract.

Complications were reported in the following cases: Delayed head-first cases 43, transverse lies 3, haemorrhages—ante-partum (unclassified) 1, placenta praevia 7, post-partum 5, secondary post-partum 2.

Instrumental delivery took place in 45 cases, the placenta being removed manually in 6 of these. Version was performed in 8 cases, the placenta being removed manually in 3 of these.

Summary of obstetric operations in 154 cases of puerperal septicaemia: No obstetric operation 72 cases (46.7 per cent.), perineal suture only 14 cases (9 per cent.), forceps, etc., 45 cases (29.2 per cent.), version 8 cases (5.2 per cent.), manual removal of placenta only 15 cases (9.7 per cent.).

The only information as to vaginal examinations during delivery was as follows: Child born before arrival of doctor or nurse, no interference necessary, 1 case; child born before arrival of doctor or nurse, but perineum sutured, 1; no examinations before delivery, 3; one examination only, 2; one examination by doctor, 1.

Fœtal conditions: Twins 3 cases, premature 9, foetus putrid or macerated 5.

Source of infection: Doubtful 71 cases; possibly conveyed by doctor 2, possibly by nurse 5, possibly from putrid foetus 2; injuries during delivery—extensive lacerations, 12; difficult forceps extraction 16, version 5, manual removal of placenta 16, packing uterus for post-partum haemorrhage 1; retained portions of placenta 15; associated infections—influenza 1, alveolar abscess 1, syphilis 3, gonorrhoea 2; from another patient—scarlatina 1, erysipelas 1.

#### SYMPTOMS.

The information obtained under this heading is of little value. The temperature rose on the second, third, or fourth day in 73.5 per cent. of the 121 cases about which particulars are available. The character of the pyrexia was very variable, but was remittent in a large proportion of cases. The accuracy of much of the information on this point is, however, very doubtful.

#### Rigors and Pyrexia.

The interval between the first rise of temperature and the occurrence of the first rigor is of interest, as giving some indication as to the rapidity of onset of the actual blood infection. Particulars on this point are available in 75 cases as follows (the first figure in each instance shows the interval in days, the second the number of cases): 0, 38; 1, 7; 2, 4; 3, 6; 4, 2; 5, 4; 6, 2; 7, 1; 8, 1; 9, 2; 10 and over, 8. It will be seen that the rigor occurred on the day of onset of pyrexia in more than half of the cases. Rigors occurred in 107 cases (74 per cent.), there were no rigors in 37 cases, and no information as to rigors in 10 cases. In 18 of the patients who died and in 6 of those who recovered there was only one rigor; in 9 and 4 respectively there were two rigors; in 9 and 2 there were three; in 12 and 2 there were four; in 3 and 0 there were five; in 15 and 10 there were more than five; and in 16 and 5 the number was doubtful. In 7 of the patients who died and in 3 of those who recovered the first rigor was on the first day; in 10 and 3 it was on the second day; in 10 and 2 on the third; in 10 and 5 on the fourth; in 4 and 3 on the fifth; in 6 and 0 on the sixth; in 4 and 0 on the seventh; in 4 and 2 on the eighth; in 5 and 0 on the ninth; in 4 and 0 on the tenth; in 1 and 1 on the eleventh; in 1 and 0 on the twelfth; in 3 and 0 on the thirteenth; in 0 and 2 on the fourteenth; in 7 and 2 the first rigor was later than the fourteenth day.

In 13 of the patients who died and in 3 of those who recovered pyrexia began on the first day. In 20 and 5 respectively it began on the second day; in 29 and 12 on the third day; in 15 and 8 on the fourth day; in 10 and 1 between the fifth and ninth days. In 1 fatal case the onset of pyrexia was on the twelfth day; in 1 fatal case on the thirteenth or fourteenth day; and in 1 fatal case between the fourteenth and twenty-first days. The day of onset was doubtful in 33 cases.

Vomiting occurred in 8 of the patients who died and in 3 of those who recovered; insomnia in 4 and 6 respectively; diarrhoea in 19 and 6; delirium in 29 and 5.

#### PATHOLOGY AND BACTERIOLOGY.

Post-mortem examinations were made in 49 cases, and the results are summarized as follows: No localized lesions, 12 cases; abdominal or pelvic conditions—peritonitis, etc., 23; thrombosis only, 11; pulmonary lesions only, 3.

The lesions observed are enumerated as follows:

Uterus—metritis and endometritis	6 cases
Peritonium and pelvic cellular tissues—	
Free fluid in general peritoneal cavity (serous 21, blood-stained 3, turbid 3, purulent 8)	21
Pus in pouch of Douglas	4
Pus in broad ligament	3
Spleen—	
Diffusent	3
Infarcts	7
Circulatory System—	
Vegetations on mitral valve	3
Venous thrombosis:	
Ovarian	7
Ovarian and inferior vena cava	2
External iliac and femoral	3
Femoral and saphenous	1
Internal saphenous	1
Uterine wall	1
Broad ligament	1
Respiratory System—	
Pleurisy, with or without effusion	5
Empyema	2
Pulmonary congestion	3
Pulmonary consolidation (abscesses in 6 cases)	9
Miscellaneous—	
Pyæmic abscesses	6
Petechial haemorrhages in various organs	7
Staining of tissues with blood pigment	2
Rapid decomposition from gas-forming organism	1

#### Blood Cultures.

The blood was examined during life in 75 cases, and streptococci were grown in over 65 per cent. A great majority of these examinations were made in one institution, and the high percentage of positive results not only indicates a very efficient technique, but also demonstrates the serious character of the infections. The cultures were generally made soon after the patient's admission and, if negative, were repeated in the event of her progress proving unsatisfactory. The following table gives some details as to the date, number, and results of the blood examinations in twenty-two cases where the particulars are available. [The detailed bacteriological findings at post-mortem examination and during life are omitted here.]

Serial No.	Day of Onset of Pyrexia.	Day of First Rigor.	Day of Blood Culture, and Result.	If Fatal, Day of Death.
2	2nd	5th	8th, Positive	13th.
3	2nd	4th	4th, Positive	7th.
5	7th	7th	12th, Positive	17th.
8	?	Nil	28th, Positive	35th.
9	2nd or 3rd	9th	8th, Positive	17th.
11	?	12th	15th, Positive	34th.
12	2nd or 3rd	6th	7th, Negative	14th.
18	?	Nil	13th, Positive	34th.
19	4th	4th	8th, Negative	Recovered.
			12th, Negative	
25	9th	9th	24th, Positive	60th.
29	3rd	3rd	11th, Positive	8th.
34	3rd	3rd	4th, Positive	11th.
35	3rd	3rd	7th, Positive	26th.
			3rd, Negative	
59	3rd	3rd	24th, Positive	Recovered.
			11th, Negative	
102	2nd	2nd	14th, Negative	Recovered.
107	4th	4th	9th, Positive	35th.
114	4th	7th	17th, Positive	14th.
115	3rd	3rd	6th, Positive	25th.
116	3rd	Nil	14th, Positive	9th.
118	2nd	Nil	8th, Positive	13th.
119	2nd	Nil	12th, Positive	7th.
120	?	Nil	6th, Positive	7th or 8th.
			7th, Positive	

#### TREATMENT.

In investigating the results of treatment, the Committee has been faced with the difficulty that a variety of different methods have been employed in almost every case, and it feels that it is quite impossible to express a definite opinion as to the efficacy of any particular method.

Some attempt has been made to group the various lines of treatment and examine the results, but the mortality in all is uniformly high, and there seems to be very little to choose between them.

#### Methods Employed, with the Exception of Drugs.

Intrauterine treatment alone was employed in 18 cases; intrauterine treatment and abdominal operation in 5; intrauterine and serological treatment in 21; intrauterine treatment and drainage of abscesses in 5; intrauterine and serological treatment, and drainage of abscesses in 8; intrauterine treatment, abdominal operation, and drainage of abscesses in 7; intrauterine and serological treatment

with abdominal operation and drainage of abscesses in 2. Abdominal operation alone was employed in 4 cases, and combined with serological treatment in 10; serological treatment alone in 49, and combined with drainage of abscess in 5; drainage of abscesses alone in 4 cases.

#### Operative Procedures.

*Intrauterine methods* were employed in 42 per cent. of all cases. They consisted of curetting, with or without douching, in 3 fatal and in 2 non-fatal cases; curetting, with drainage, in 5 and 2 respectively; douching in 6 and 1; douching, with drainage, in 7 and 2; swabbing in 1 and 3; exploration, with or without douching or swabbing, in 17 and 2; exploration, with drainage, in 13 and 2.

*Vaginal operation* (drainage of the pelvis through posterior fornix) was employed in 14 fatal and in 6 non-fatal cases.

*Abdominal Operations.*—Of these, 21 were performed on fatal cases and 9 on non-fatal cases. The mortality after abdominal operations was 70 per cent. The operations were as follows: Drainage of abdomen in 8 fatal and 3 non-fatal cases, ligation of thrombosed veins in 9 and 2 respectively, ligation of thrombosed veins with removal of one or both appendages in 3 and 1, ligation of thrombosed veins with removal of uterus and appendages in 1 non-fatal case. The mortality after operations for pelvic thrombosis was 75 per cent. Appendage removed for salpingitis in 1 fatal case and 2 non-fatal cases.

#### Serological Treatment.

*Antistreptococcal serum* was administered in 101 cases. As regards dosage, 50 c.cm. or less was given in 13 fatal cases and in 1 non-fatal case; 50-100 c.cm. in 8 and 6 respectively; 100-150 c.cm. in 3 and 3; 150-200 c.cm. in 2 and 4; over 200 c.cm. in 20 and 3. In 37 cases the amount is not known. The largest dose was 1,050 c.cm., in a fatal case.

*Antigonococcal serum* was administered in 1 fatal case.

*Vaccines* were administered in 13 cases in all. Mixed streptococcal vaccine in 3 fatal and in 3 non-fatal cases; autogenous in 1 and 4 respectively; in 4 fatal cases and 1 non-fatal case the nature of the vaccine was not stated: streptococcal and staphylococcal vaccine was given in 1 non-fatal case, and *B. coli* vaccine in 1 fatal and 1 non-fatal case.

#### Drugs.

The principal drugs employed were quinine (administered in 15 fatal and 7 non-fatal cases), collosol manganese (in 3 and 3 respectively), and coagulen ciba (in 9 and 2). The following drugs were also used: collosol argemum, collargol, novarsenobillon, ergot, acriflavine, chloramine, calcium chloride, iron, strychnine, digitalis, ammonium carbonate, calomel, infundibulin, adrenaline, parathyroid.

Other methods of treatment, employed in a few cases, were fixation abscess, drainage of pleural cavity, opening of pyaemic abscesses, blood transfusion, and vaginal tampons and packs.

#### Summary of Results of Treatment.

1. Intrauterine methods with or without other operative procedures: Total cases, 66; mortality, 78.7 per cent. Intrauterine methods, no other operative procedure: Total cases, 41; mortality, 80 per cent.

2. Abdominal operations with or without other operative procedures: Total cases, 30; mortality, 70 per cent. Abdominal operations, no other operative procedure: Total cases, 14; mortality, 71.4 per cent.

3. Serological treatment with or without other operative procedures: Total cases, 104; mortality, 72 per cent. Serological treatment, no operations: Total cases, 47; mortality, 76.5 per cent.

#### PERIOD OF SURVIVAL.

The number of days patients lived after the onset of pyrexia (in 100 cases) is shown in a concluding table.

Two patients survived 3 days, one survived 4 days, seven survived 5 days, nine survived 6 days, and four survived 7 days; 23 per cent. died within a week of onset of pyrexia. Five patients survived 8 days, eight survived 9 days, six survived 10 days, five survived 11 days, three survived 12 days, four survived 13 days, and two survived 14 days; 33 per cent. died within a fortnight of the onset of pyrexia. Six patients survived 15 days, three survived 16 days, one survived 17 days, two survived 18 days, one survived 20 days, and 31 survived over three weeks.

It will be noticed that 23 per cent. of cases died within a week, and 31 per cent. survived three weeks or longer. Of cases in the latter group, about 50 per cent. had definite thrombo-phlebitis.

#### RESULTS.

The general mortality rate in the series of 154 cases is 76 per cent. This is a very high percentage, but it has to be remembered that the report deals only with cases of puerperal blood infection, and that fatal cases have been included, irrespective of *ante-mortem* symptoms.

## Reports of Societies.

### ENCEPHALITIS LETHARGICA.

At a meeting of the Manchester Medical Society on April 1st, the President, Professor G. R. MURRAY, in the chair, Dr. D. E. CORE opened a discussion on encephalitis lethargica.

Dr. CORE first described a typical case of average severity in a young man of 24, and then dealt with certain symptoms and sequelae in detail. As regards the diagnosis of encephalitis lethargica, it was important to remember that no particular symptoms were essential; often enough the condition escaped recognition as an illness by the patient and his friends, and might only be revealed as such in the light of the after-course. The view that it was possible to establish a diagnostic scheme based upon symptoms was, he believed, untenable, and the present tendency to do so was responsible for the many erroneous diagnoses. Apart, however, from objective signs of implication of the nervous system, he had been increasingly impressed by the interesting relation existing between the symptoms and the patient's consciousness. In normal life there was a reasonably close parallelism between objective behaviour and the personality of the individual; a man who was acting in an uncontrolled way usually showed signs of mental uncontrol, one who seemed to be profoundly unconscious was as a rule unconscious, and a delirious patient was generally not aware of his surroundings. In encephalitis lethargica, however, this association did not appear to obtain. The most restless and uncontrolled patient was quite often capable of giving a remarkably clear and logical account of his sensations without any evidence of psychical uncontrol. It was notorious that the patient somnolent to the point of coma was usually able to answer questions and to give information demanding considerable concentration; the same phenomenon was observable in delirious patients. Furthermore, the ability to memorize subsequently events occurring in their environment at such times was considerable. In other words, instead of the normal association between the psychical state and the somatic symptoms, there was a dissociation which was anatomical rather than psychical, and which, he thought, was the most characteristic feature of the disease. The same principle was at work in the frank emotional loss of control that was liable to affect children as an after-state, and in the somatic want of control in the young adult with symptomatic paralysis agitans. From the standpoint of diagnosis this dissociation was, in his opinion, of greater value than objective signs of cerebro-spinal implications.

Dr. W. ST. CLAIR McCURE said that encephalitis lethargica was an infectious disease spread by "carriers": the organism responsible was universally distributed, but, happily, the majority of people were immune to its attack. A chart had been prepared showing that all ages were liable to attack, but that the incidence was most heavy between the ages of 10 and 20 years. Males and females were about equally attacked, and there was no special preponderance of cases in any one particular occupation. Bad environment appeared to predispose to an attack. In a series of 244 patients in 1924, 20 per cent. died; after twelve months 20 per cent. had apparently recovered, and 60 per cent. had residua of some kind, two-thirds of which were of a Parkinsonian character. Similar figures for 50 cases which occurred in Manchester in 1920 and 1921 were: mortality rate 56 per cent., recovery rate (three years after onset) 14 per cent., and incapacity rate 30 per cent. Taking into consideration wrong diagnoses and non-recognized cases, 15 to 20 per cent. probably represented the recovery rate, though it differed in different epidemics. The prognosis in any individual case was guesswork, but it was comforting to know that complete recovery was possible even in cases which at first appeared hopeless, and it was notable that some who did not recover were not, however, totally incapacitated. In many the disease process came to a standstill, and a useful and more or less happy existence was possible. Hiccups might occur as one of the symptoms of encephalitis lethargica, and be the one and only sign of the disease.

Epidemics of hiccup and encephalitis, however, did not as a rule run concurrently: in Manchester, in 1924, a hiccup epidemic preceded the encephalitis epidemic. In December, 1923, and January, 1924, there was a generalized epidemic of hiccup in the city. The attacks consisted of persistent hiccup lasting three to ten days, unaccompanied in the majority of cases by other symptoms, though some few patients exhibited drowsiness. The sufferers invariably recovered without sequelae, and an inquiry twelve months later had not so far resulted in the discovery of any post-encephalitic signs amongst them. In the investigation of cases of encephalitis lethargica special inquiry was made amongst 1,200 contacts for a history of hiccup, but only two were discovered. The households attacked by encephalitis lethargica were not those attacked by hiccup. Amongst the encephalitis lethargica patients hiccup was one of the symptoms in about 3 per cent. There was no evidence here favouring the view that the two diseases were associated, though such a possibility was not excluded. During the first three months of 1924 influenza of a mild type was said to be prevalent. It was not, however, until the middle of March, when the epidemic of encephalitis had subsided, that influenza of a severe type became evident. Special inquiry amongst contacts showed that it was the exception for a case of influenza to have occurred amongst them (10 out of 1,207), nor did the patients themselves suffer from influenzal symptoms. Influenza, though said to be present, did not to any extent invade households attacked by encephalitis. Influenzal cases had not given rise to encephalitis lethargica, nor had cases of the latter disease given rise to influenza. A study of the epidemic waves of influenza and encephalitis in Manchester showed that there was no correlation in point of time between the two diseases and provided no evidence in support of the contention that they were associated in any way one with the other.

Professor J. H. DIBLE, speaking from the pathological side, was in full agreement with the previous speakers as to the difficulties in clinical diagnosis. The first three cases in which he performed autopsies turned out to be tuberculous meningitis. He wished to draw the attention of the society to the experimental pathology of the disease. At the onset of its epidemic phase analogy with poliomyelitis suggested that it might be transmitted to apes and investigated upon the line so successfully followed by Flexner and his associated workers in the latter disease. Early experiments, however, particularly of McIntosh and Turnbull in this country, had failed to infect these animals, and it was not until 1919 that Strauss, Hirschfeld, and Loewe reported successes from America. These workers then reported further successes with naso-pharyngeal washings and cerebro-spinal fluid as well as with brain material as the source of the infecting agent, and they claimed that the rabbit and not the monkey was the animal of choice for this work. Early in 1920 Levaditi and Harrier claimed to have transmitted the disease to rabbits, and about the same time McIntosh published an account of similar successful inoculation of monkeys in series, and from monkey to rabbit. The speaker himself had, since 1920, been attempting to convey the disease to the lower animals, and gave details of many attempts to transmit the infection to rabbits, using material derived from ten cases of the disease. These experiments invariably failed, whatever type of material was used as inoculum and by whatever route that inoculum was introduced. Attention was drawn to the existence of two schools—one claiming that production of the disease in animals was so possible as to be used as a diagnostic measure with the cerebro-spinal fluid, whilst the other school, of which Levaditi was the protagonist, claimed that the disease was definitely inoculable, but only with difficulty, and that success was rare. His own personal experience had been entirely negative. Recently Flexner, whose authority in this type of work was very great, had published the results of a very large series of attempts made in conjunction with Ames. All material from cases of encephalitis had failed to infect: a positive result was obtained in one instance, but this was with cerebro-spinal fluid from a case of cerebral syphilis and not of encephalitis. Such results called into question again the validity of all the published positive results. The matter was one of great difficulty and

was complicated in many ways, one of the most confusing questions being the relation of the encephalitis produced in animals by certain workers to that which the herpetic virus of Grütner was capable of setting up. Much more work was required before the matter could be regarded as settled, but, in the opinion of the speaker, the claim to have transmitted the disease to animals was as yet unsubstantiated.

Dr. C. J. C. FAIR agreed with the previous speakers as to the difficulty of diagnosis. Out of sixteen cases admitted as encephalitis lethargica under his care at Mansall Hospital, eleven were proved to be other conditions, including tuberculous meningitis, brain abscess, and brain tumour. Some of these cases could not be diagnosed on physical examination alone. He had seen the typical dissociation of which Dr. Core had spoken in a case of cerebral abscess situated in the region of the basal ganglia. One case admitted as mumps proved to be encephalitis with parotitis. In three out of five of the more acute cases admitted herpes labialis was present. In one of these cases the sister of the ward also developed herpes labialis, though without any nervous signs, and it was an interesting question whether she should be regarded as having suffered from the disease in a latent form or, on the other hand, having been immune to it. One of the acute cases had shown excitability to a marked degree. He mentioned one case of inversion of sleep rhythm in a child who was more intelligent and cunning during the night than in the daytime; he also wrote a much clearer hand at night.

#### TREATMENT BY ARTIFICIAL LIGHT.

At a meeting of the Section of Electro-Therapeutics of the Royal Society of Medicine on April 17th, Dr. STANLEY MELVILLE presiding, three communications on artificial light sources in treatment were made. One was by Sir Henry Gauvain, on the organization and work of the light department in the surgical tuberculosis hospital at Alton; the second by Dr. G. Murray Leveick, on the selection of apparatus for the production of "artificial sunlight" (a term which both he and Sir Henry Gauvain criticized on the ground that it was clumsy and misleading); and the third by Professor Sidney Russ and Dr. Peacock, a brief report on some experiments on ultra-violet radiation.

Sir HENRY GAUVAIN explained that by light treatment he meant treatment by light produced by artificial means in distinction from sunlight. Only since the end of the war had he been able to realize a cherished ambition to have a properly equipped light department at Alton. He had been long convinced of the value of sun treatment for surgical tuberculosis, and on the ground of that practical experience, rather than on the scientific principles of light therapy (which were not yet fully established), he found justification for a department in which artificial light sources were employed to supplement or take the place of sunlight. Light treatment was necessarily very expensive. The initial cost of the lamps was only the beginning of a considerable and constantly recurring expenditure. At Alton an admirable generating plant in charge of a highly skilled engineer was available, so that it was a comparatively simple matter to select a ward as near to the power house as possible in order to reduce the length of cable, and to dig a connecting trench in which two cables were laid. By the kindness of Dr. Axel Reyn, whose paper read at the British Medical Association meeting at Portsmouth, in 1923 (*JOURNAL*, September 22nd, 1923, p. 499) was very useful in this connexion, he was permitted to study the methods employed at the Finsen Institute at Copenhagen. Dr. Reyn and his co-workers pinned their faith to the open carbon arc, both for the general light bath and for local treatment. Sir Henry Gauvain said that at Alton he decided not to limit the choice so rigidly; nevertheless he made this source the principal one, and, determining that his own department should be based on the exact technique of the Finsen Institute in this respect, he succeeded in getting the services for six months at Alton of one of Dr. Reyn's trained sisters in order that the nurses in his light department might be instructed in the Finsen method. The installation consisted of two 75-ampere carbon arc lamps, each capable of treating simultaneously eight ambulant patients and three recumbent patients. With regard to

the other sources employed, during recent years a good deal of attention had been given to short-wave or ultra-violet radiation, and the value of such radiation—in rickets particularly—had been demonstrated. Therefore he made provision for mercury-vapour lamp treatment in his department, as well as for treatment by the tungsten arc, the iron arc, and other methods. The short-wave rays had proved somewhat disappointing. They had little penetrating power, although great superficial necrotic action, and he thought it was very necessary to exercise caution in using them. Until more was known about their mode of action his whole instinct was to proceed very carefully indeed. In the entire work of the department constant and responsible supervision was very necessary, and for that reason the department was so arranged that everything was under the immediate observation of the sister in charge. Treatment went on ordinarily from 8 in the morning until 7 in the evening, after which every lens and compressor was cleaned and the installation got in order for the next day. For general light baths a treatment lasting two and a half hours, and given on alternate days, was sufficient. While this treatment was being given the heads of the patients were protected by adjustable asbestos shields, they were given water to drink, and at the conclusion the ambulant cases went away for a douche and the recumbent cases were thoroughly washed. By the use of compressors, which exsanguinated the part, much deeper penetration of the light was possible. He found it of great value to intermit the light baths after a certain period of treatment. In the treatment of surgical tuberculosis he regarded the Finsen method as the principal, and the other light methods as accessory. The mercury-vapour lamp and the tungsten arc were not so valuable in the general treatment of this condition as the carbon arcs, though they might prove useful to prepare the way for the latter, and they were certainly advantageous for local uses, as in the treatment of sinuses and discharging glands. The long-wave infra-red rays were of some value in local treatment also, though he was doubtful about the claims sometimes made on their behalf. He had also a 110-volt Kromayer lamp, which he employed for local treatment. He exhibited photographs of his various apparatus, including a tunnel arrangement for subjecting a limb or the whole body to concentrated light, and mentioned that he was now experimenting on the production of portable lamps designed for patients who were too ill to be brought into the department. He added that at Alton the light department had the great advantage of the exclusive services of a laboratory research worker.

Dr. MURRAY LEVIER said that he had come to rather different conclusions from Sir Henry Gauvain as to the relative value of different light sources. So far as the treatment of surgical tuberculosis was concerned, he deferred entirely to Sir Henry Gauvain's opinion, but he thought that the difference between his own conclusions and those of Sir Henry was due to the rather different type of case dealt with. In his own work at St. Thomas's he had had to do with rather older patients than those who came under Sir Henry Gauvain's care, and they were suffering more or less from general illness and debility. His own preference was for mercury-vapour lamps as against the open arc. He was convinced that any disfavour into which mercury-vapour lamps had fallen was chiefly due to the erroneous idea that it was the ultra-violet rays alone in sunlight that produced therapeutic effect, and therefore that the lamp must be employed by itself. He had found the greatest advantage in combining mercury-vapour lamps with long-ray lamps, and with this combination he had obtained much better results than with the open arc. Debilitated patients who had been treated unavailingly by the open arc had subsequently responded favourably to the mercury-vapour combination. The results obtained with this combination among debilitated, rickety, and tuberculous children were superior to those obtained with the open arc. Even during exposure the difference between the two arrangements was manifest. The staff all said that they felt enervated and listless while the open arc was in action, whereas with the mercury-vapour lamp the effect was refreshing and exhilarating. With the open arc also it

was impossible to have the slightest draught in the room on account of the flickering. The mercury-vapour combination was valuable for its uniform intensity; and, moreover, was cheaper to use than the open arc. An efficient reflector was a very necessary adjunct to mercury-vapour work. It was true that the mercury-vapour combination required very skilful and experienced handling and exactness in administration, on account of the extreme intensity of exposure. He had just returned from a visit to the Finsen Institute, and while he was full of admiration for all he saw there he thought it a pity that the institute should confine itself entirely to the carbon arc method.

Dr. PRACECK, in the name of Professor Russ and himself, gave an account of some experiments on ultra-violet radiation which went to substantiate the view that the fluorescence of the skin surface in the ultra-violet beam was an immediate protective phenomenon, and that pigmentation which came later was a sign of the failure of fluorescence to protect the structures. If pigmentation was aimed at as the standard in treatment it was tantamount to producing an effective action against the very source of the treatment employed. It was noticed that smearing with vaseline enabled the skin to withstand a much greater intensity of radiation from the mercury-vapour lamp.

## Rebuelus.

### MUIR'S "PATHOLOGY."

Of excellent textbooks on physiology we have quite a number, and the high position of physiology in this country is probably more the result of, than the reason for, that fact. Recently a distinguished physiologist expressed the opinion that the pick of medical students who had originally set out with the idea of practising medicine were acted for physiology, though he was willing to allow that some of these who escaped the net might develop and become pathologists!

Pathology has not been so well served hitherto in the matter of textbooks. Treatises for the fully fledged, exhaustive monographs for the expert to consult, and soulless descriptive catalogues of morbid anatomy, there have been in plenty; but no "clear account writ fair and broad" to attract the student to a subject which, after all, is the basis of medicine and surgery. We therefore gladly welcome Professor ROBERT MUIR'S *Text-Book of Pathology*.<sup>1</sup> Our foremost British pathologist, he has exceptional qualifications for the task: a long and intimate acquaintance with the various aspects of pathology, many years of experience as a teacher, with the ability to present the subject simply, and, above all, the rare gift of going straight to the heart of a problem. "Ordered selection" used to be the principle that governed the Glasgow school of artists, and the same words could be used to describe briefly the method adopted in this product of the Glasgow school of pathology. The subject-matter is certainly compressed—not, indeed, at the expense of lucidity or interest, though the reader feels that here and there a more extensive consideration of such special problems as he may be specially engaged upon might have been given. It is a testimonial to the book that we realize that the author has much in reserve, much more that he could have imparted, but that he has deliberately sacrificed this in order to preserve due balance.

The reader is presented with a sound and attractive view of the subject by a master who appreciates the fact that those whose interest is aroused will seek to learn more, and the awakening of the desire to learn more is the test of good teaching. The student is introduced first to the changes that result from disturbances of nutrition, the various tissue degenerations, and the disturbances of the circulation; these learned, the phenomena of inflammation, the reparative processes, infection, and immunity are unfolded in easy sequence. The chapter on tumours which follows may be taken as a good example of the characteristics of the book; the varieties and characters of each tumour are succinctly and lucidly expounded, and the

<sup>1</sup> *Text-Book of Pathology*. By Robert Muir, M.A., M.D., Sc.D., F.R.S., Professor of Pathology, University of Glasgow. London: Edward Arnold and Co. 1924. (Med. 8vo, pp. vii + 774; 433 figures. 35s. net.)

etiological factors and experimental observations are discussed judiciously and with insight; nothing is omitted that is of prime consequence; the problems are stated calmly and speculations are entirely excluded.

It is difficult in this book to separate special from general pathology: the transition from the one to the other is gradual. The chapters on the circulatory system, the respiratory system, and the blood-forming system may be considered to partake of both characters. The abdominal organs, the nervous system, bones, muscles, reproductive organs, and endocrine glands are more definitely special pathology. Every chapter is well done, and the reading of each leaves us with the feeling that we have at least mastered the fundamentals, but we want to learn more.

Still, at the same time, we would not have this textbook enlarged. The student with the multiplicity of subjects for examinations before him, and generally with a modest purse, desires a reasonably priced book, readable, informative, and up to date, and the general practitioner and consultant seek an authoritative and well proportioned account of a subject which they have not always practical opportunities for investigating. To them Professor Muir's textbook will be welcome. As for the pathologist, teacher, or laboratory worker, the book will be a friendly companion. The illustrations are numerous and well chosen. Reading the publisher's prospectus a fear arose that photomicrographs would prove, as they generally do, disappointing in bringing out the salient features that are shown by good drawings, but the fears were groundless, for, with few exceptions, the illustrations are clear and demonstrative. Messrs. Arnold are to be congratulated on the excellent get-up of the book. There are a few unimportant typographical errors that may be corrected in the second edition, which is probably on the way, if it has not by this time actually arrived. It will be a matter for wonder if the *Text-Book of Pathology* does not run through as many editions as Muir and Ritchie's *Bacteriology*.

#### OPERATIVE SURGERY.

A NEW work, in two volumes, entitled *Modern Operative Surgery*,<sup>2</sup> by Mr. H. W. CARSON, has recently been published. The editor, who has himself written several excellent sections, has called to his aid a series of collaborators of such standing as must ensure a welcome for his book. The object, which was to provide a textbook well and truly describing the technique of modern operative surgery, appears to us to have been to a very considerable extent achieved. The work is uneven, as all such works must be, not necessarily because some of the labourers were not worthy of their hire, but because the things they had to do were not all equally exciting or fruitful. There are always sections which have to be covered—sections which no one particularly wants to do, because out of them it is difficult to strike fire. It is all very much like casting a play, one imagines; there are fat parts and thin parts. The editor has wisely ruled out multiple alternatives and obsolete methods, leaving us with a compact text.

The book opens with a section on anaesthetics by Dr. J. Blomfield, and this is followed by another on the conservative treatment of tuberculosis, by Sir Henry Gairdner, who describes the methods in use at Alton and Hayling Island.

General orthopaedics is dealt with by Mr. R. C. Elmslie, who also writes on tendon transplantation and on amputations. He has limited himself strictly to the operative side of the question, and these parts are very well done. Very clear accounts are given of a number of the more commonly used methods; the text is not burdened by a number of alternatives. Professor Hey Groves follows with an admirable exposition of the more mechanical methods of dealing with fractures, illustrated by figures from his well known book. The various nailing, plating, and grafting operations are made to look so easy that a good deal of disillusionment is in store for such readers as have hitherto had little experience.

Mr. A. J. Walton writes on spinal surgery, on abdominal

ptosis and adhesions, and on the thyroid gland. The section on the treatment of ptosis will be read with considerable interest by all. A very useful summary of the results of the division of membranes shows that such measures alone are seldom adequate to produce a cure, but that if followed by a course of physiotherapy the majority of patients are restored to perfect health. It is very necessary that the surgeon should be a firm believer in these measures, otherwise he is not likely to be able to control his patients subsequently. Which is to say that it seems very possible that an operation (quite regardless of what was done) is the essential, and acts as a form of major suggestion. Mr. Walton thinks it doubtful whether caecum and stomach fixations are as satisfactory as is generally believed. We doubt whether they are, in point of fact, at all generally believed to be satisfactory. Certainly the majority of surgeons in the great centres of England employ them rarely. Mr. Walton's views on the treatment of intestinal stasis, and on the plexus of that disease as an entity, are lucidly and even brilliantly expressed. We trust that his large experience may help to discourage others.

Operations upon the nerves are described by Mr. Harry Platt. He introduces a considerable amount of anatomical, pathological, and clinical matter of the greatest importance, and all of it is well put. The descriptions of operative technique could not be bettered; this is in every way an admirable section.

When we are told that Mr. Sampson Handley has written part of this book it will not be hard to guess what part it is. His views are well known, and will here be found to be again expressed with that urbanity, clarity, and persuasiveness which mark all his written work. On this occasion he goes into considerable detail on the treatment of melanotic sarcoma and of late rodent ulcer in addition to his usual account of breast surgery. Both of these additions should stimulate interest very considerably, particularly in the case of the melanotic tumours. Mr. Handley thinks that the virulence of this disease is overestimated. One of his own patients was alive fifteen years after operation. We fear that there is some ground for his contention that few surgeons, if any, have tackled these growths in a sufficiently scientific spirit.

Another section which makes this book most valuable is Mr. Grey Turner's article on the surgery of the liver and its excreting apparatus. We venture to think that no more original presentation of the subject has been seen for years. It will appeal especially to surgeons in what we may call their middle period—to those who have had a considerable experience of these cases but who have not become absolutely crystallized. A valuable feature of each section throughout the book is the addition of a short piece on the results of the various methods described.

Mr. Carson has himself taken over the greater part of abdominal surgery. His contributions are competent and well illustrated. Sir Berkeley Moynihan has sent him an account of the operation of pylorotomy as performed by himself, and Mr. Ernest Miles performs a like service on the technique of abdomino-perineal removal of the rectum. Apart from these, Mr. Carson's own parts are very well written, and a wise discretion has been used in the choice of procedures to be described.

It is impossible to do more than indicate the contents of the book; it is well produced, print and illustrations being very clear, and covers the whole field of surgery, including the eye, nose, and ear, and gynaecology; it is a valuable addition to the surgeon's library.

#### A TEXTBOOK OF PEDIATRICS.

In the third edition of his book, *The Practice of Pediatrics*,<sup>3</sup> Dr. KERLEY has received the assistance of Dr. GAYLORD W. GRAVES. The first edition appeared in 1914, and the book, if not yet of age, has at least passed the more dangerous years of childhood and has a reasonable expectation of growing up. The method of treatment is that commonly adopted in systematic textbooks of this subject; the early chapters deal with the special physiology and anatomy of

<sup>2</sup> *Modern Operative Surgery*. Edited by H. W. Carson, F.R.C.S. Eng. In two volumes. London and New York: Cassell and Co., Ltd. 1924. (Vol. I, pp. xiii + 784, 364 figures, 2 plates; Vol. II, pp. xi + 784, 376 figures, 4 plates. 43 s., net the two volumes.)

<sup>3</sup> *The Practice of Pediatrics*. By C. G. Kerley and G. W. Graves. Third edition, revised and reset. Philadelphia and London: W. B. Saunders Company. 1924. (Roy. 8vo, pp. 922; 4 coloured plates, 152 figures. 45s. net.)

infancy and childhood, with dietetics, and with general hygiene, and the remainder of the book gives an account of disease in childhood under the usual division of systems.

The authors in this methodical way take the reader over the entire territory of their subject, over ground that is well known, and into the regions of the rare diseases. They present a great mass of miscellaneous information, but perhaps their most interesting chapters are those where they rely mainly on their own experience and are sparing of references to authorities and "the literature." The difficult subject of infant feeding is handled in this more personal way, and is expounded with conviction and common sense; in it there is enough and not too much of that "lore of nicely calculated less and more." A clear account is given of the use of unsweetened condensed milk supplemented by starch and sugar, which is recommended for feeble and dyspeptic infants, until, after a few months, raw milk meals are gradually introduced. The chapter on diseases of the stomach and intestines—a group which in America yields perhaps more varieties and clinical types than in this country—is also of special merit; it contains an interesting account of visceroptosis, including falling of the stomach, with good x-ray illustrations.

In other sections personal experience does not blend so well with the general stock of knowledge, and the presentation of the facts fails a little in interest and coherence. The illustrations, too, are not of a high standard, and the citation of clinical records is often too brief to be really helpful. As a whole, however, the book can be recommended as a trustworthy guide to the subject, and one that is written by able and experienced physicians.

#### A GUIDE TO GENERAL PRACTICE.

*Consultations du Médecin-Praticien*,<sup>4</sup> by Dr. FRED. BLANCHOD, is an unusual book. It is intended to be a guide to the treatment of ailments met with daily in general practice, and is based on an experience of fifteen years as a country doctor. In his introduction the author quotes the epigram attributed to Dr. Franek of Vienna: "When I was a young doctor I had a hundred remedies for a single disease, but now that I am old I have only one remedy for a hundred diseases." The routine of many years in general practice does not appear to have simplified Dr. Blanchod's outlook in such a way, for he remains equipped with an armamentarium full of resources, but purged of many academic weapons. He begins with some good advice on common and avoidable errors, and distinguishes two varieties of mistakes of which the practitioner may be guilty: the first are errors which he calls academic, and the second are such as put the patient's life in danger, of which the commonest is that the doctor does not make a diagnosis because he has no time to think. To give an example, he observes, a constipated baby is most frequently a hungry baby, and it must be given nourishment instead of a purge.

The different ailments which a general practitioner is likely to meet with are arranged in alphabetical order and discussed from the practical point of view. In the treatment of everyday complaints, such as colds in the head and indigestion, French practice differs more from English than in that of the hospital type of disease, and judging from this book it appears also to be more versatile. No doubt, therefore, rural practitioners in this country would often find it useful to consult a book like this.

#### DYSPEPSIA.

DR. SOLTAN FENWICK's work on *Dyspepsia, its Varieties and Treatment*, makes a welcome reappearance after having been out of print for several years. The second edition<sup>5</sup> does not differ from the first in its scope and general arrangement, but a thorough revision has been carried out, and the chapter on displacements of the viscera has been rewritten. The book is broad-based on personal experience, and quotations from the literature are

used with discretion and appropriateness, giving the impression that, while the author is deeply read in all that pertains to the subject, his individuality is never in danger.

After a preliminary chapter on the varieties of dyspepsia and their differential diagnosis, the several kinds are considered separately, a chapter being devoted to each. Thus abnormalities of secretion, failure of muscular power, inflammations, disturbance of the nervous mechanism, displacements, foreign bodies, infancy and old age, and disease of other organs, constitute the headings under which the subject is considered, and they embrace all the varieties of indigestion that any practitioner is ever likely to meet, and some, it is almost certain, he never will. In the latter category are the cases due to the presence of living creatures in the gastro-intestinal tract. Dr. Fenwick has collected a formidable array of well authenticated cases in which lizards, frogs, tritons, slugs, caterpillars, worms, leeches, beetles, maggots, larvae, or chrysalides were responsible for intractable dyspepsia. Nevertheless, although more or less a clinical curiosity, such a cause of intestinal trouble cannot be wholly ignored. It is not, however, by its inclusion of the out of the way that the book claims attention, but by its wide everyday applicability; and it is a tribute to the author's acumen of observation and lucidity of expression to say that it is easy to recognize the types that he describes, and to translate the book into actual practice. Dr. Fenwick is above the influence of fashion in treatment. He utters a note of warning against the indiscriminate removal of teeth in dyspeptic cases, and points out that, though oral sepsis may give rise to gastritis, just as suppuration anywhere in the body may produce the disease, the effect is not generally due to the direct swallowing of pus from the gums. He emphasizes the importance of not allowing the condition of the teeth to deflect or defer a search for other causes for the dyspepsia.

There is a suggestive section on the chronic gastro-enteritis of infants. The inflammatory nature of the disease is demonstrated by sections showing round-celled infiltration between the glands of the mucous membrane of the stomach and intestine, which may subsequently organize and produce atrophy of the glands and cirrhosis of the mucous membrane, and attention is drawn to the far-reaching effect of this process. "It is not generally understood that the gastric disease contracted, and apparently cured, in infancy is capable of exerting a deleterious influence upon the functions of digestion in adult life." Ample evidence is produced to support this obviously important statement.

As a whole the book is exceedingly well written in a fluent style which engages the mind, and in this respect might well serve as a model; to read it is to find a source of pleasure and much profit.

#### THE ANALYSIS OF OILS.

THE fifth edition of *Allen's Commercial Organic Analysis*,<sup>6</sup> Vol. II, treating of fixed oils, fats, and the like, has made its appearance. This volume does not differ notably from the plan of its predecessor in the last edition. It contains descriptions of all the fatty materials, the rare as well as the more familiar, which are known to published literature. Descriptions of the rare materials are properly limited to recorded observations of characters and the result of analytical or test reactions; commoner articles receive more detailed notice according to their importance. Descriptions of the latter include information of the occurrence, geographical source, and mode of preparation; the chemical and physical data from which the behaviour of the material in various circumstances may be predicted or explained are supplied also. These matters have an important bearing on the methods to be followed in analytical procedure, analysis being the express subject of the book. Analytical directions appear usually in the form in which they were presented by the investigators who devised them. Methods for the analysis of fats are in general derived on an arbitrary plan; this is the inevitable consequence of the nature of fatty materials. No chemist dealing with fats

<sup>4</sup> *Consultations du Médecin-Praticien*. Par le Dr. Fred. Blanchod. Paris: J. B. Baillière et Fils, 1925. (Roy. 8vo, pp. 584. Fr. 35.)

<sup>5</sup> *Dyspepsia, its Varieties and Treatment*. By W. Soltan Fenwick, M.D., B.S. Lond. Second edition, revised. London and Philadelphia: W. B. Saunders Company, 1924. (Med. 8vo, pp. 515. 24s. net)

<sup>6</sup> *Allen's Commercial Organic Analysis*. Edited by Samuel S. Sadtler, S.B., Albert C. Lathrop, A.B., Ph.D., C. Ainsworth Mitchell, M.A., F.I.C. Vol. II. Fifth edition, revised and in part rewritten. London: J. and A. Churchill, 1924. (Med. 8vo, pp. ix + 807; 23 figures. 30s. net.)

may ignore the paths trodden by his predecessors in this wilderness of chemistry. Accordingly as much importance attaches to the records of experience in the use of methods as to the details of directions concerning them. In this respect the book is a particularly rich storehouse of information. Sections dealing with subjects of prominent interest are contributed by chemists of distinction in their special spheres. They are men well known as investigators and authors of commentaries on their respective subjects. It is a frequent cause of complaint that in technical books little heed is paid to the relation between technical processes and the chemical facts on which they are founded. In many cases, it is true, the latter are but imperfectly known, yet it is desirable, for the sake of a better understanding of the subject as well as for the higher development of chemistry, that nothing should be left obscure in the borderland between chemistry and its technical applications. It is satisfactory to note in the volume before us a continued improvement in this respect. We do not observe any section of the contents calling for special mention, and it will suffice to say that the book maintains its character as a leading work on the subject.

### NOTES ON BOOKS.

In the volume on *Toxicology* Dr. FRANK P. UNDERHILL has collected a great deal of useful information, and some parts of it are written clearly and effectively. It is sadly lacking, however, in some of the qualities most desired in a book of instruction. Some paragraphs exhibit signs of the sort of haste with which a candidate writes answers to questions set for examination; others resemble the jottings prepared from a lecture. On page 168 there is an idiomatic use of the word "will" which may have been handed down from Mercian English but is not now current. It reads, "One gram will undoubtedly cause death in an adult, although recovery has followed from the ingestion of more than three ounces." Evidently the author means "One gram may." But there are other and many instances of incautious expression: ergotism, for instance, seems to be confused with ergotism, and there are cases in which the treatment of the subject is ill considered. The author states as an example of how poisoning may not be induced that arsenic in large doses may act as an irritant to the stomach, causing vomiting, with prompt ejection of the poison, so that few or no toxic symptoms result. Our comment is that tartar emetic would have furnished a better example of the fragment of truth contained in the statement. Yet even with tartar emetic it would have been proper to point out that the danger increases with the magnitude of the dose, for with a larger dose a larger residue is likely to escape ejection. There is a contrast between the effects of zinc sulphate and those of zinc chloride, as well as between the effects of concentrated and dilute solutions of the latter, but these facts are not made clear by the author's description. So far as we have observed, the poisonous property of oxalates receives no other notice than that contained in the warning that alkalis are ineffective as antidotes to oxalic acid. The selections are capricious. Acetic acid is treated as a poison, but hydrofluoric acid is unnoticed. No objection need be raised against a description of toxic effects arising from the absorption of magnesium sulphate, but attention to effects so rare is inconsistent with the omission of reference to quinine as a poison; death has been reported from an overdose of quinine on a number of occasions; the symptoms were well known in the time of Jonathan Pereira, who described them minutely, and its chronic effects are of the greatest importance in malarial districts. Again, there is much disorder in the arrangement of subject-matter. We are at a loss to know the reason for such hasty production. If the author was racing against another writer it would have been sport to see his competitor's product. If he was not racing he ought to begin again and write it afresh. We are sure he could do better.

The authorities of the Washington University of St. Louis, Missouri, U.S.A., last year established in their medical school a lectureship in the history of medicine. Dr. M. G. Scelig, Professor of Surgery, who delivered the first course of lectures, has published them under the title of *Medicine: An Historical Outline*.<sup>6</sup> The subject is obviously too vast to be treated adequately in so small a volume as this, but the author probably succeeded in interesting his audience and in

<sup>6</sup> *Toxicology, or the Effects of Poisons*. By Frank P. Underhill, Ph.D. Philadelphia: P. Blakiston's Son and Co. 1924. (Post 8vo, pp. ix + 232. 1s. 2s. 6d.)

<sup>7</sup> *Medicine: An Historical Outline*. Dr M. G. Scelig, M.D. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 12s. (Cr. 8vo, pp. xviii + 227; 43 plates. 11s. 6d. net.)

arousing intelligent curiosity, which may be satisfied by the study of larger works. The lectures were delivered in the winter semester of 1924, and this fact suggests that they were hastily prepared for the press; the supposition is strengthened by certain small errors and omissions. For instance, there is no mention of Bretonneau and his work on diphtheria, and although Glisson is referred to as an anatomist his claims to fame as a pathologist and first describer of rickets are ignored. No doubt in the next edition Sir Francis Bacon, Lord Verulam, will no longer appear as Lord Francis Bacon, Stromeyer will regain his Christian name of Louis instead of George, and Robert Knox the anatomist will no longer be in danger of confusion with the great Scottish reformer. We cannot think that "a medical nobleman" is a happy translation of "medicus nobilis" as applied to Sydenham. Did Harvey really write "omnis vivum ex ovo"? Dr. Fielding Garrison writes an interesting foreword in which he misquotes a Bab ballad, but even an imperfect acquaintance with the Gilbertian classics is to be welcomed. The interest of the book is enhanced by forty-eight plates and a frontispiece, mostly reproductions of well known portraits.

### MEDICAL AND SURGICAL APPLIANCES.

#### A Bone and Plate Clamp.

MR. MURICE SINCLAIR, C.M.G., M.B., Ch.B., Major R.A.M.C., Ret. (London), has devised the instrument shown in the illustration mainly for bone-plating operations. With it such operations, he says, are much shortened and greatly simplified, as the fragments can be securely held in their alignment while the fracture is bridged by means of a specially modified plate, which is firmly gripped by the clamp or clamps to the upper and lower fragments of bone. The bone can now be safely and readily drilled and the plate secured by means of screws without loss of alignment, without obstruction to vision, and without those obstructions which frequently arise during the fixation, especially of the initial screws. The bone and plate clamp may be used singly or in pairs, one for each main fragment of a fracture. After the fracture has been repositioned they clamp and hold the bone fragments and the metal plate

*in situ*, until no longer required, when they are easily removed. The clamp used for the bones of the upper limb is similar to that used for the lower, but is of lighter construction.

A clamp consists of a male stem and a female tube, and has an over-all measurement of 14 in. for the lower limb. The male stem is made of 5/16 in. round steel, is flattened and hooked at one end in order to aid the gripping of the bone, while the other end is threaded, and has a keyway, slotted along the underside, to prevent the hook from rotating when the instrument is being used. The female tube is 10 in. long and takes the male stem inside. At one end it has a jaw brazed to the outside, and at the other end it is fitted with a butterfly nut, which takes the threaded end of the male stem. The portion projecting beyond the nut is sheathed in a thimble of metal, in order to prevent undue destruction of rubber gloves. The bone plates are a modification of Lane's, and the surface of the plate which is applied to the bone is concave, with a "kick up" (as it is technically called) between each hole. These plates fit the convexity of the bone accurately, and the "kick ups" prevent slipping of the plate on the bone. When the plates are firmly gripped by means of the clamps greater security is obtained.

Mr. Sinclair considers such an instrument and plate essential to obtain the results detailed in the article in the *BRITISH MEDICAL JOURNAL* of November 17th, 1923. The clamp and plates have been made by Messrs. Down Bros., 21, St. Thomas's Street, S.E.1.

#### Carrying the Thermometer.

"A. J. V. B." tells us that for some years he has been carrying his thermometer tucked on to one of the sides of his binaural stethoscope. The thermometer is in an ordinary metal case, and is held in position by two rubber bands cut from a piece of drainage or irrigator tubing; the case is easily turned to one side for opening. He finds many advantages in thus carrying a thermometer; among others, that it makes one article less to gather up on starting out.

### THE TREATMENT OF MENTAL DISORDER.

In the evidence given before the Royal Commission on Lunacy and Mental Disorder on behalf of the British Medical Association<sup>1</sup> emphasis was laid on the need for more flexibility in arrangements for dealing with mental cases. It was pointed out that if the best possible is to be done for mental patients the facilities for treatment and the types of accommodation must be sufficiently various to suit the particular form their illness assumes. It is quite understandable that the Legislature should be reluctant to relax laws intended to protect the persons and estate of those unable to care for themselves and their affairs, but fortunately the existing laws have been elastic enough to enable progressive movements to develop, so that experience has been obtained of the extent to which some relaxation of the law can safely be permitted. A particularly difficult question is that of the treatment of persons of unsound mind who need care and control in nursing homes, and it is of interest and importance to observe that this type of accommodation has been utilized on a large scale in homes connected with the Royal Hospital at Morningside.

Professor G. M. Robertson gave an account of this new development at Morningside in his annual report for 1924, a summary of which we published on March 7th (p. 475). When, seven years ago, further accommodation for private patients became necessary, the managers, recognizing that the public had become more and more averse to sending patients suffering from mild and curable attacks of mental disorder into mental hospitals, gave careful thought to the particular form which any new accommodation should take. They decided to establish, quite detached from the mental hospital, nursing homes in which patients in the early stages and with curable forms of mental disorder might be received. The expectation was that they might recover without being certified or entering a mental hospital; the report shows that this expectation has been fully justified. During the whole of last year four fully equipped nursing homes, accommodating about fifty patients, have been working in the suburbs of Edinburgh, and a country mansion for convalescent patients accommodated a dozen or more. The managers have now purchased another mansion with 250 acres of land, and in this large building the scheme will be further developed. In view of its bearing on possible legislation this new venture would seem to merit the closest study, and we venture to suggest that Professor Robertson would help still further the solution of the legislative problem if he gave details of the cases treated in these homes, classified from a social as well as from a psychiatric standpoint. In the evidence given on behalf of the British Medical Association it was suggested that a convenient social classification of mental disorders would divide its subjects into the "mentally unsound," for whom measures of detention and control are necessary, and

the "mentally ailing," for whom such measures are not required. It is for the former class in particular that some modification of the law in England is desirable. As things are at present many of them could not be treated away from home, except in mental hospitals or under single care, without a breach of the law, though their mental condition would warrant their being dealt with in suitable homes other than actual mental hospitals. Such cases are in general somewhat vaguely described by psychiatrists as mild, early, or curable, and it has not been made sufficiently clear to the lay mind what type of case would benefit by proposed changes in the law, nor for whom at present inadequate provision is made. No doubt the majority of the cases treated in the homes in connexion with Morningside would come under the category of the "mentally unsound" as above defined, and it is for this reason that a more detailed description of these cases would probably be found of considerable assistance in the endeavour to solve the problem of future legislation.

The fact that the family medical attendant continues to treat his own patients in these nursing homes, as he is accustomed to treat medical and surgical cases, is a particularly valuable and important feature in this new development. Not only is psychiatry in this way brought into the closest relationship with general medicine, but it gives confidence to both patients and relatives and does away with that sense of isolation from life which removal into a mental hospital is apt to engender. It can hardly be insisted too strongly that mental disease, which in its last analysis must be regarded as the objective expression of a disordered, biologically inferior, or unduly sensitive physical organism, presents arduous problems only to be solved by a closer union of psychiatry and medicine. For this reason we welcome a new development, which not only affords mental patients widened facilities for treatment, but also brings the psychiatrist and general physician into closer co-operation. The value of these homes must also be greatly increased by the fact that they are organically connected with Morningside Mental Hospital. Professor Robertson is of the opinion that such homes should be under disinterested management, and should be started only under the aegis of bodies which already have some experience of the provision needed; he points out also that such homes must be under the supervision of the department (the General Board of Control) which keeps under observation places for the treatment of patients in an analogous condition. Any homes or institutions in which patients of unsound mind are under treatment, whether they place themselves under control by their own wish as voluntary boarders or whether they are under certificate, should be supervised by a Government department, to prevent, as Professor Robertson says, scandals which might arise from the adoption of inefficient methods and from the possibility of injustice to certain patients.

The report goes on to show that voluntary admission has grown into such favour in Scotland and to such proportions as to amount to a revolution in practice with regard to mental diseases. At the present time, of all the private patients admitted to mental hospitals in Scotland 40 per cent. entered as voluntary patients; this percentage is increasing year by year. A similar state of affairs obtains in England; thus the Retreat at York and Bethlem Hospital have a large proportion of voluntary boarders, and the Maudsley Hospital only admits voluntary patients, many of whom are suffering from severe psychoses. From these facts it is obvious

<sup>1</sup> Printed in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of January 17th, 1925.

that many of the well-to-do subjects of mental disorder are able to obtain treatment on a voluntary basis which forms an ideal alternative to certification. The poorer classes are, however, much less favourably placed, especially in England, where the law does not admit of voluntary admissions to the rate-aided mental hospitals, except in the case of the City of London Mental Hospital. As a result of this many persons, not certifiable but sorely in need of treatment and willing to undergo it voluntarily, either drift into a severe psychosis or, in a number of instances, commit suicide. Faced with such cases the practitioner is almost helpless, as there is no place within the patient's means to which he can be sent. In this respect the law is obviously in serious need of amendment. Even in Scotland, where there is no legal bar to the voluntary admission of poor patients, the fact that the parish councils receive the lunacy grant (amounting to about 2s. 9d. weekly for each patient) only in the case of certified patients means that this method of reception is seldom adopted. In the annual report of the Aberdeen Royal Asylum Dr. R. Dods Brown says that one rate-aided voluntary patient is resident in the hospital; he refers also to the interesting fact, which has already been pointed out in this JOURNAL, that several parishes in Argyllshire have agreed to allow suitable cases to reside as voluntary boarders in the district mental hospital. A passage quoted from the last annual report of the Commissioners of the General Board of Control for Scotland reveals the Board's sympathetic attitude towards the tendency to allow patients to enter asylums voluntarily for skilled treatment in the earlier stages of mental illness when the prospects of recovery are great. If pauper patients also were permitted to enter asylums voluntarily by a rearrangement of the lunacy grant, "the certification of patients, which is not necessary for medical purposes, would fall from the present level of about 100 per cent. to 60 per cent. or even less of the patients admitted to asylums. Certification of the insane would then fall into its proper place of a social and legal necessity."

The Scottish Board of Control also remarks: "In the treatment of all such cases the Board have come to the conclusion that district boards, either individually or in combination, and the authorities of royal asylums, should be empowered to establish nursing homes, hospitals, outdoor and indoor clinics, particularly by arrangement with the managers of general hospitals throughout the country, where anyone desiring advice, care, and treatment may receive it as a voluntary patient. It is felt that such an arrangement would tend to dispel the natural fear that the person seeking advice, care, and treatment might at any time be certified as insane and detained against his own free will." This quotation admirably outlines the kind of developments which we hope to see in the near future. It indicates the varieties of accommodation necessary for the treatment of the various forms of mental illness. Such schemes will doubtless call for additional expenditure at the outset, but they will prevent many persons from becoming a permanent charge on the community, and must in the long run exert an appreciable effect upon the general mental health of the community.

Further information about the voluntary boarder system and the treatment of early cases in Scotland will be found in our report (at page 798) of the evidence given by Professor Robertson, Dr. Comrie, Dr. Carswell, and Dr. Marr before the Royal Commission on Lunacy and Mental Disorder.

## SCARLET FEVER.

LIKE all other advances in knowledge, those which we owe to Drs. George and Gladys Dick for their painstaking work on scarlet fever open up more territory even before the newly won ground has been completely surveyed. These two research workers have taught us that a particular variety of streptococcus originates scarlet fever, that the symptoms of the disease are caused by the toxin of this germ, that the tissue cells of a recovering patient provide a protective antitoxin, and that scarlet fever may be produced by experimental inoculation with haemolytic streptococci and cured with an antitoxin serum. If we accept all this—and there is strong experimental evidence in its favour, as we have often observed in our comments on this work as it has been published piece by piece—there remain two unsettled questions of outstanding urgency. One is, How are these specific streptococci to be distinguished from other streptococci? The other is, How can the antiserum be prepared and accurately standardized? Both these problems have been tackled by the Dicks, and they have written about these questions in two papers which appear in the *Journal of the American Medical Association* for March 14th, 1925.

First, with regard to methods of recognizing scarlet fever streptococci. The streptococci have always been a troublesome genus to the systematists, and in spite of their prodigious labours at classification we are not yet in possession of any quick and accurate means of distinguishing the different kinds of streptococci one from the other. The haemolytic streptococcus of scarlet fever resembles other haemolytic streptococci in its morphology; its appearance in tubes of culture media presents nothing sufficiently distinctive; and, in the hands of most workers, fermentation reactions and other refinements of bacteriological diagnosis have not separated the scarlet fever streptococcus from kindred cocci. Even agglutination reactions have disappointed their early promise, and the Dicks conclude from the studies of others that the agglutination test is not a reliable means of identifying scarlet fever streptococci. They find, however, that the haemolytic streptococci of scarlet fever can be recognized by the specific toxin they produce, and suggest the following ingenious method of carrying out the test. A blood broth culture is incubated for three or four days passed through a Berkefeld filter, and the sterile filtrate diluted 1 in 500 with normal saline. The essence of the test is to determine whether or not this diluted culture filtrate contains the scarlet fever toxin; if so, the suspected streptococcus was the genuine scarlet fever germ. The question is answered by mixing 1 c.cm. of the sterile filtrate with 1 c.cm. of serum from a convalescent scarlet fever patient; another 1 c.cm. of sterile filtrate is mixed with 1 c.cm. of salt solution to act as a control. Both mixtures are incubated one hour, and skin tests made on a person known to be susceptible to scarlet fever, using 0.1 c.cm. of each mixture. At the same time a control test is made with 0.1 c.cm. of the ordinary standardized skin test solution to determine susceptibility to scarlet fever, and this control, of course, should be positive. If the mixture of filtrate and salt solution also gives a positive reaction; while the filtrate convalescent serum mixture gives a negative result, it may be concluded that the particular streptococcus under examination was capable of producing a toxin that is neutralized by convalescent scarlet fever serum. It was therefore a scarlet fever streptococcus.

We admit the logic of this test and respect the

ingenuity with which it has been devised, but foresee many pitfalls. Neither the suspected toxin nor the serum of the convalescent patient can be standardized, and a test depending on the neutralization of two opposite substances, neither of which can be measured exactly, is likely often to mislead. Even if these difficulties were overcome the necessity of performing the test in a convalescent volunteer is likely to limit its wide application. But we acknowledge that the Dicks have established an important scientific fact, which in certain circumstances may be put to practical use.

The second paper—on the therapeutic results obtained with concentrated scarlet fever antitoxin—carries this research a step further into the fields of everyday medicine. More than a year ago Drs. George and Gladys Dick reported that they had produced a scarlet fever antitoxin by immunizing horses with scarlet fever toxin, and they now publish a preliminary report on the preparation, standardization, and dosage of concentrated antitoxin. This, in brief, is their method. A blood broth culture of scarlet fever streptococci is incubated six days, filtered, and the sterile toxin injected into horses subcutaneously in graduated doses, beginning with 20 c.cm. and increasing to a litre. After preliminary tests have shown that the horse serum has developed antitoxin the horse is bled and the serum concentrated. The antitoxin content is standardized against a stock toxin. The Dicks have found by experience that 1,000 skin test doses of toxin, if injected without previous immunization, produce a clinical condition resembling a mild attack of scarlet fever, and they chose the amount of antitoxin required to neutralize this dose of toxin as a basis for standardization. The concentrated antitoxin is standardized so that 1 c.cm. of concentrated serum neutralizes 1,000 skin test doses of toxin, the tests being carried out by incubating mixtures of toxin and antitoxin, and then examining for unneutralized toxin by performing skin tests on susceptible individuals. Here again, although the method is logical and ingenious, its applicability is limited by the fact that all standardizations have to be carried out on selected human volunteers.

There seems little doubt that this concentrated antitoxin is a useful agent in the treatment of scarlet fever. From the figures the Dicks give we note that there were far fewer complications and sequelae of scarlet fever in 29 cases treated with antitoxin than in 15 control cases which did not receive antitoxin; in fact, in 21 moderately severe cases complications and sequelae were limited to 2 cases of otitis media. The antitoxin was injected intramuscularly, and the best results followed when it was given early in the disease. The immediate benefit obtained from the serum treatment was evidenced by fading of the rash, improvement in the patient's general condition, and disappearance of fever.

A third paper in the same number of the *Journal of the American Medical Association*, by Dr. O. B. Nesbit, on the Dick test and immunization against scarlet fever, deserves a word or two of comment. Dr. Nesbit examined 2,162 school children with the Dick test, and found 40 per cent. positive. Many years must elapse before much can be learnt from the after-history of these children with respect to scarlet fever, but it seems that in the last six months two cases of scarlet fever have appeared among the Dick-positive group and none among the Dick-negative. We note that in one school the administration of toxin to 67 pupils did not result in any loss of time. In one

school 57 children were submitted to Schiek and Dick tests at the same time, and every child was present the following day for the reading of the Dick tests. Dr. Nesbit concludes that 65 per cent. of pupils susceptible to scarlet fever were rendered immune by injection with three doses of scarlet fever toxin.

#### CUSHING'S "OSLER."

*The Life of Sir William Osler*,<sup>1</sup> by Professor Harvey Cushing, has appeared; a review copy reached us on Monday. It is a rather big book in two volumes, making together 1,438 pages. A preliminary glance shows that it is a biography in which the subject is allowed to tell his own story as far as possible by letters and those informal notes and postcards which Osler showered about him, to the great joy of recipients. It is well illustrated, and one observation that springs to the eye is how little Osler changed in physical appearance from the time when he was a professor at McGill University, Montreal, in 1878, to the time when he was Regius Professor of Medicine at Oxford. We are given a photograph of him, taken there early in 1915, standing in characteristic attitude with his arm linked in his son's, that only son—"a son after my own heart"—whose death on active service some two years later cast so deep a shadow on the two years more William Osler himself was to live. The book is in three parts; the Canadian period (1849-1884) and the period of the United States (1884-1905) fill the first volume; the second is concerned entirely with the Oxford period (1905-1919). We intend to publish a review in an early issue.

#### THE ADRENALS AND SEXUAL DEVELOPMENT.

It is known that tumours of the adrenal gland are associated with precocious puberty in the male and precocious development of secondary male characteristics in the female. A few years ago Krabbe of Copenhagen, in a paper written in English and published in America,<sup>2</sup> advanced a theory to explain this strange fact. The sexual gland in the early stage of development lies close to the portion of the genital ridge where the adrenal cortex is developed. Laulanic, Jonesik, Nagel, and Coert came to the conclusion that the primitive ovary is hermaphroditic; this view was confirmed by A. Kohn as lately as 1920. While the testis develops nearly directly from the undifferentiated original mass, the ovaries pass through a stage in which the cortical part may be considered female, but the deeper or medullary part male or testicular. Krabbe reproduced the figures given by Kohn: in the male is shown pure testicular development; on the external surface is the germinal epithelium, from which has developed medullary cords which will become tubuli seminiferi; between these cords are the interstitial cells. In the development of the female sex gland the epithelium of the germinal ridge forms medullary cords as in the male, with interstitial cells centrally situated, but the cortical part of the primitive gland contains primordial follicles and follicles with a zona granulosa. Normally the male sexual gland tissue of the primitive ovary undergoes atrophy and disappears. Should some of the male germinal cells become included in the developing cortical cells of the adrenal gland, they may later in life develop a tumour consisting of interstitial cells. It might be argued that if this theory were correct they would be seen in the tumour, but it is very difficult to distinguish interstitial cells of the testis from cortical adrenal cells. While there is masculinization of females with adrenal tumours, there is no feminization of boys who have had adrenal tumours. According to Krabbe, this can be

<sup>1</sup> *Sir William Osler*. By Harvey Cushing. Two volumes. Oxford University Press. (Price 37s. 6d.; India paper edition, 1 vol., 50s.)

<sup>2</sup> *New York Medical Journal*, 114, 1921.

explained on the view that in male embryos there is a pure testicular stage, while in females there is an ovario-testicular stage. According to Krabbe, tumours of the adrenal cortex are developed from an abnormally placed adrenal gland. The male part of the primitive ovary has not remained rudimentary and disappeared, but has become a part of the cortex of the adrenal gland and developed as a part of it. On this hypothesis the tumour cells developed from the adrenal cortex are not developed from adrenal cortical cells, but from cells which represent the medullary male part of the ovary, so that the tumour cells secrete a hormone characteristic of the male; virilism in girls, it is suggested, is produced in this way. The presumption of a condition of hermaphroditism in the female sex gland in the early stages of development is therefore held to explain precocious puberty in males and virilism in females associated with tumour of the adrenal gland. Several recorded cases of ovario-testis support this view. That of Blair Bell is of particular interest. In it an ovario-testis without any abnormality in the adrenals was associated with masculinization. Removal of the gland led to disappearance of the male characters. Microscopical sections of the ovario-testis showed a central testicular portion with infantile seminal tubules surrounded by interstitial tissue with an outer capsule of ovarian tissue, containing Graafian follicles. Berblinger has recently described a very similar case. A girl at the age of 12 began to grow a beard, but menstruation set in at the age of 16. At the age of 21 a tumour the size of a walnut was removed from the right labium. Psychological development—which till then was indifferent—became now typically female. The tumour was an ovario-testis containing typical Graafian follicles externally, and internally rudimentary testicular tissue. It may be noted in this connexion that Steinach and Sand found that intersexuality in mammals could be caused by combining ovarian and testicular implantation in the same individual castrate. Recently Kemp,<sup>1</sup> in an article also written in English, has subjected these views of Krabbe to criticism. As to the morphological factors upon which is based the view that the primitive ovary is bisexual, he holds that the medullary cords of the ovary and seminiferous tubules of the testis may be considered as homologous. Similarly the cortex of the ovary and the superficial covering of epithelium of the testis may be regarded as homologous. The process of development in the primitive sexual gland is accentuated in both sexes, though in varying degree, more strongly in the ovary than in the testis; the sexual gland, as regards organic shape and structure, is similar to the other internal genital organs, and this dualism is maintained in a somewhat greater degree in the ovary than in the testis. A point of great importance is that as soon as it can be determined to which sex the primitive sexual cells in the medullary cords belong, they are female. The first decisive feature distinguishing the primitive ovum from the primitive sperm cells is the primitive follicle, the single-layered stratum granulosum that forms around the primitive ova—the oögonia—but not around the spermatogonia. The primitive follicles are to be seen in the medullary cords at a very early embryonic stage. In man they are to be found from the sixth foetal month, but are said to disappear shortly after birth. This statement is, however, not universally accepted. Kemp bases his view against Kohn's theory, upon which Krabbe relies, on the great difficulty of deciding whether the medullary cords bear any definite male or female characters until primitive follicles are developed. We cannot agree with Kemp in his assertion that "there is no probability, let alone proof, to warrant attributing the power of hormone production to the interstitial cells when the corresponding generative tissue is

not present." He concludes with the following statement: It is not merely absolutely unproved, but also highly improbable, that the medullary cords of the ovary or the connective tissue cells lying between them could become displaced into the adrenals, and, being further developed there, produce a testicular hormone. It is known, however, that the embryonic epithelial cells of the semiaiferous tubules, even at birth, are not of a characteristic form like the primitive ova. The subject is of very great interest from many points of view, and before it can be settled further evidence is required.

#### SCANDINAVIAN MEDICAL LITERATURE.

Those to whom English is the native tongue are greatly interested and not a little gratified by the growth of the study of the English language in the three great Scandinavian countries. Sympathy with them is traditional in England, where in some parts is a strong strain of Scandinavian blood, evidenced by place names and also by the construction of the common surnames. The extent of the movement in Scandinavia is indicated by the existence of flourishing societies. The Anglo-Danish Society has its headquarters in Copenhagen, the Anglo-Swedish in Stockholm, with branches in the university towns Upsala and Lund; the Anglo-Norse, established in Oslo (Christiania) has branches in Stavanger and Bergen. These societies are large and growing, and the *Times Literary Supplement*, from which we take this information, has stated recently that among their members there is "a quite extraordinarily high standard of English speech and culture." Evidence of the growth of a preference for English as a second language is afforded also by the fact that Scandinavian men of science show a growing disposition to publish the results of their researches in our language. We have mentioned this on two or three occasions within the last few months when giving an account of recent papers, and another instance is afforded by the papers of Krabbe and Kemp noticed in another paragraph this week. With one exception the articles to which we refer were published in the series of Scandinavian medical periodicals published under the general title *Acta*. The *Acta* dealing with surgery, gynaecology, medicine, laryngology, pediatrics, skin diseases and syphilis, and radiology, are edited in Stockholm. The place of publication of *Acta Pathologica*, in which Kemp's paper appeared, is Copenhagen. Further, it will have been observed that Professor Moelgaard of Copenhagen not only contributed to our columns a paper on the gold treatment he has devised for tuberculosis, but wrote his book on the subject in English. First-rate scientific work is being done in the Scandinavian countries, and we have also much to learn from them in matters of administration; Denmark, for instance, has solved its Poor Law problem with a completeness England may well envy. From the other point of view there is this to be remembered, that English is spoken by many more people who read than any other language, and that, owing to its directness and conciseness, when well written, and to the ease with which it assimilates Latin and Greek roots, it lends itself well to the expression of scientific facts and speculations. We may therefore look forward to a not distant time when the work done by the medical profession in Denmark, Norway, Sweden, and, we may add, Holland, will be better known than it is to-day, very much to the advantage of medical science throughout the world.

#### THE USE OF THE ELECTRO-CARDIOGRAPH.

WE have received two inquiries from a practitioner who has acquired an electro-cardiograph and who wishes to know what use he can make of it in estimating the suitability or otherwise of patients to undergo general anaesthesia, and in determining in insurance cases that a particular life

<sup>1</sup> *Acta Pathologica et Microbiologica Scandinavica*, vol. 1, fasc. 2, 1924.

is uninsurable or requires an additional premium. The electro-cardiograph, like Mckenzie's polygraph, has served a useful purpose in demonstrating the exact nature of many forms of cardiac irregularity and the site of their production in the conducting tissues of the heart. The practitioner who has studied and understood these graphic records has gained additional knowledge, and this knowledge will enable him to deal more intelligently with many problems in his clinical work. These graphic records, however, do not reveal more than certain disorders or disturbances in different areas of the heart, and they give no indication as to how far the functional efficiency of the heart has been affected by them. To take a familiar example—that of auricular fibrillation: we can get a very clear picture of the irregularity in an electro-cardiographic tracing, but we get no information as to whether the patient is suffering from cardiac distress or requires treatment. In former days some were content to determine the suitability of a patient for an anaesthetic by means of a stethoscope only, but that method has now fallen into disrepute. Similarly, in the present day some have decided the treatment of a cardiac patient by electro-cardiographic tracings only, and without seeing the patient, but such a method is not likely to establish itself as a common practice in English medicine. Reverting to the original questions, we should say that the electro-cardiograph cannot be utilized for deciding the suitability or otherwise of a patient for general anaesthesia. Whatever hidden disturbance the tracings may reveal the practitioner will have to decide by other methods of examination as to their effect and as to the strength and efficiency of the cardiac action. As regards life assurance the same standard applies, and the examiner should not be overmuch influenced by a cardiographic tracing. From the insurer's point of view the less said about it the better, for if a board of directors read that a r-wave is turned upside down or that the r-wave is split they will anticipate the worst and may reject the applicant at once.

#### MALARIA CONTROL IN PALESTINE.

THE Haifa Malaria Research Unit, maintained by the American Joint Distribution Committee in co-operation with the Government of Palestine, is under the control of Dr. I. J. Kligler, who was formerly associated with the Rockefeller Institute; it has recently issued its report for 1923. The unit is primarily concerned with the endeavour to establish malaria control on an extensive scale in Palestine at a low cost. Much valuable information has been obtained by it during the last few years about the geographical prevalence of malaria, the types of mosquitos concerned, and the nature of their breeding places; while, in addition, practical education of the public in malaria control has been undertaken. With a view to the permanent elimination of mosquito breeding places, the engineering division of the unit has made detailed surveys of swamps, and has stimulated co-operation between settlements and villages in drainage schemes. Experience gained during 1923 has shown that many of the more important swamps can be eliminated with relatively small expense, and that, with the aid of small financial grants, the settlements themselves will be able to eradicate permanently some of the chief sources of malaria. The laboratory of the unit, by its clinical investigations and special research work, has been able to render valuable service. The report deals in detail with these various activities, and is well illustrated by photographs, charts, and statistical tables. The chief breeding places of the malarial mosquito appear to be the coastal marshes, the overgrown wadis (rivulet beds), and the cemented cisterns for domestic water storage. These large coastal marshes require radical drainage, which will involve considerable expense. One such swamp has already

been drained as the result of a concession granted to the Athlit Salt Company, and another company has agreed to drain the largest of these areas—the Cabara swamp—on the basis of a land concession to be granted by the Government. The Hule marshes above Lake Meiron, which lies north of the Sea of Galilee, are the largest swamp areas in Palestine, and render the surrounding plain uninhabitable. Important drainage operations are also being undertaken by the Jewish National Fund and other Jewish agencies, active supervision being supplied by the Malaria Research Unit to prevent outbreaks of malaria or unnecessary delays in the work. During the year under review wide areas, hitherto infested with malaria, have thus been rendered habitable. Five drainage schemes were also independently completed by the unit, and surveys were made for several other schemes to be put into operation during 1924. All these undertakings deal with breeding places solely, or chiefly, responsible for the malaria of large groups of the population. They are all planned on most economical lines, and in every case part of the small cost is borne by the people to be benefited. Education of the native population by bringing about the closing of the cisterns, the proper use of spring water, and the treatment of accumulations of stagnant water, will effect a marked improvement. In each area as it was taken into consideration the programme was as follows. From January to March, when there was no mosquito breeding, a complete survey was made of possible breeding places and of the human parasite and spleen rates, followed by intensive treatment of carriers. A systematic house-to-house search for hibernating mosquitos was also organized. These preparatory steps aroused public interest and paved the way for the actual campaign, which started in April with the beginning of the anopheles breeding season and went on until the heavy rains, which, in 1923, did not occur until the end of December. The chief methods of control employed were drying by intermittent damming of streams, and cleaning pools and streams with or without larvicides, including a crude paraffin and castor-oil mixture, Paris green, and a watery solution of cresol. The statistical tables show that a marked decrease in the malaria incidence followed the application of these measures. Quinine prophylaxis was only employed temporarily when mosquito control had broken down. No evidence was obtained that the incidence of infected mosquitos was higher than in Macedonia or other malarial areas.

#### BOSTON PSYCHOPATHIC HOSPITAL.

THE report of the trustees of the Boston Psychopathic Hospital for the year ending November 30th, 1923, is of considerable interest. The trustees have reason to be proud of the achievements of their hospital. They are alive to the need for a better understanding of mental troubles of all sorts, and "particularly cherish the fact that, side by side with the treatment of symptoms and diseases, there is a steady attempt to get at fundamentals for understanding the disorders of mental life." The nature of the treatment employed and of the research which is being prosecuted is shown in the numerous reports submitted to the board of trustees, all of which together make up the present document. There is, first of all, the report of the director of the hospital, Dr. C. Macfie Campbell, giving a general presentation of the work of the institution. The detailed analysis of this work is found in the reports which follow of the chief medical officer, the out-patient department, the biochemical laboratory, the psychology department, the neuro-pathological laboratory, the department of therapeutic research, the chief executive officer, the social service department, and the department of occupational therapy. The manifold activities of the hospital reflected in this list show how varied are the attempts to grapple with the problems of mental disease, both from the stand-

point of ameliorating the patient's state and of arriving at a fuller understanding of the true nature of mental disorder. There are many difficulties in the way, and many prejudices to be overcome. Ignorance of what is being done to solve the problems of mental disease is surprisingly widespread, and Dr. Campbell has to admit that "the number who realize the scope of the work of the hospital and who grasp its relation to the general health problems of the community is not large." Dealing with existing prejudices, he expresses the opinion that "we have not altogether emancipated ourselves from the mediaeval attitude to mental disorder, and certainly not from the tyranny of words." His particular instance of the tyranny of words is that of "insanity." In a recent article on the treatment of mental disorders Dr. Edward Mapother warned his readers of "the power of words to stereotype thought"—the futility of being satisfied when a disease is given a name, and when a statistical prognosis is advanced based on that name. With us, in recent years, the word which has been most assailed because of its tyranny is "asylum"; and it was in the hope of removing the stigma associated with that name that the term "mental hospital" has come into use. It was not, of course, the change of name that mattered so much as the change of conditions which helped to give that name its reproach. As the British Medical Association has said in its recent Memorandum of Evidence to the Royal Commission on Lunacy: "More important, however, than the terms used, if the best possible is to be done for those who are mentally disordered, are the arrangements provided and the conditions governing them." An institution whose primary medical object is not treatment does not become a "mental hospital" by calling itself such. "The hospitalization of asylums"—a phrase associated with the strenuous advocacy of Professor G. M. Robertson—must steadily continue and progress. Patients in a mental hospital should be afforded the same medical facilities as would be due to them in a general hospital. Many patients admitted to mental hospitals suffer from bodily as well as mental illness, the latter often the outcome of the former, and such cases specially demand skilled medical treatment and skilled nursing. "So long as general hospitals have no special service for patients with mental disorders," says Dr. Macfie Campbell, "a transfer to a psychopathic hospital will be necessary; but when, in the course of time, physicians and nurses shall in their curriculum have had adequate psychiatric training, many patients will remain in the wards of a general hospital who are at the present time transferred to a psychopathic hospital." From what has been said in these columns on many occasions it may be judged that we endorse Dr. Macfie Campbell's views on this matter, and would wish to see, side by side with the hospitalization of asylums, a more widespread practice of treating many mental cases in general hospitals. This would prove beneficial to patients, physicians, students, and nurses alike.

#### THE TAUNGS SKULL.

Dr. R. Broom, F.R.S., whose contributions to anthropology and comparative anatomy have made his name well known, has sent to *Nature* (April 18th, p. 569) an account of an inspection of the Taungs skull which he made during a recent visit to Johannesburg. Professor Dart, who described the skull and applied the name *Australopithecus africanus*, gave him every facility. With regard to the geological age of the being, Dr. Broom says that it can safely be asserted that the skull is probably not older than Pleistocene times, and perhaps even as recent as the *Homo rhodesiensis* skull. Though, therefore, the skull is not likely to be older than what we regard as the human period,

the age of the specimen, Dr. Broom says, in no way interferes with its being a true "missing link" and the most important hitherto discovered. He would put it earlier than *Pithecanthropus* in the evolutionary stem, and much earlier, therefore, than *Coanthropus*, which "has a human brain with still the chimpanzee jaw. In *Australopithecus*," Dr. Broom continues, "we have a being also with a chimpanzee-like jaw, but with a subhuman brain. We seem justified in concluding that in this new form discovered by Professor Dart we have a connecting link between the higher apes and one of the lowest human types. . . . While nearer to the anthropoid apes than man, it seems to be the forerunner of such a type as *Coanthropus*, which may be regarded as the earliest human variety, the other probably branching off in different directions."

#### LISTER MEMORIAL LECTURE.

It was decided at a meeting held at the Mansion House, London, in October, 1912, that the public commemoration of Lord Lister's work should consist of three parts. One is the tablet, with medallion and inscription, placed in Westminster Abbey; another is the monument erected in Portland Place, London, and unveiled in March, 1924; the third is an International Lister Memorial Fund for the advancement of surgery. In order to carry out the scheme for the establishment of a memorial fund, it was resolved at a meeting held in July, 1920, to award a sum of £500, together with a bronze medal, every three years, in recognition of distinguished contributions to surgical science, the recipient being required to give a lecture in London. At that meeting the Royal College of Surgeons of England undertook to become the trustees and administrators of the fund, and with the approval of the general committee of the fund the trust was transferred to the College, subject to certain provisions. One of these is that the award is to be made by a committee consisting of representatives of the Royal Society, the Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, the University of Edinburgh, and the University of Glasgow. We announced last July that the first award of the Lister Medal, with the honorarium, has been made to Sir W. Watson Cheyne, Bt., F.R.S., who was for many years intimately associated with Lister in his work. Sir Watson Cheyne's lecture will be given at the Royal College of Surgeons, Lincoln's Inn Fields, on Thursday, May 14th, at 5 p.m.

THE first Lady Jones Lecture before the University of Liverpool will be given by Sir Robert Jones, K.B.E., F.R.C.S., on Tuesday, May 12th. The lecture was founded by Mr. John Rankin in memory of Sir Robert Jones's wife, who died a few years ago—a lady regarded with affectionate esteem by a large number of members of the profession. The lecture is to be given every third year. The subject of the first is "Crippling due to fractures: its prevention and remedy."

WE regret to learn that Sir John MacAlister has been compelled by ill health to resign the office of Secretary to the Royal Society of Medicine, which he has held since its formation some twenty years ago. The Society finds it necessary to proceed at once to the appointment of a successor. An advertisement stating the conditions and terms will be found elsewhere in this issue.

WE regret to announce the deaths of Sir Arthur W. May, K.C.B., late Medical Director-General, Royal Navy, on April 20th; of Dr. Robert J. M. Buchanan, late professor of forensic medicine in the University of Liverpool, on April 19th; and of Dr. Reginald Dudfield, medical officer of health for Paddington, also on April 19th.

## TUBERCULIN TESTS IN CATTLE.

Born "certified" and "Grade A tuberculin-tested" milk must only be collected from cows previously tested with tuberculin and proved by this test to be "negative reactors," and therefore presumably free from tuberculosis. Relying on this guarantee the public has come to look upon these special milks as free from all danger of causing tuberculosis in the consumer, and has therefore regarded them as safe for children. That these cleaner milks are incomparably purer food than ordinary milk no one would deny who has seen the precautions with which such special milk is collected or has studied the stringent regulations which govern the production and distribution of these specially designated milks. There is no reason to doubt that the trust which the public has placed in "certified" and "Grade A tuberculin-tested" milk has been in any way unwarranted; and in view of what we are about to say concerning tuberculin tests it is well to recollect that the health of cattle used for collecting these milks is inquired into also by tests other than the injection of tuberculin. The cows are periodically examined by veterinary surgeons, the premises are regularly inspected, and a high standard of cleanliness is insisted on by the Government regulations. But the actual testing of the cattle with tuberculin, which has made the strongest appeal to the laity, has not always been regarded with the same confidence by farmers and veterinary surgeons.

Of the three methods of performing this test—the subcutaneous, the intradermal, and the ophthalmic—the first is the one which has been used most generally in this country hitherto, and it depends upon the fact that the temperature of a tuberculous cow rises to a higher level after the injection of tuberculin than does the temperature of a cow free from tuberculosis. All physicians will agree that the recording of the body temperature by means of a clinical thermometer is not such a simple feat as it sounds, and if experience is necessary in ascertaining the correct temperature of a willingly co-operating invalid, how much more skill must be requisite for determining the temperature curve of a cow at regular intervals after the subcutaneous injection of tuberculin in an ordinary cowshed?

### THE TUBERCULIN COMMITTEE'S REPORT.

Veterinary surgeons and farmers have been aware of these difficulties for a long time, and in 1921 representations were made to the Ministry of Health by Viscount Astor, Viscount Elveden, and Mr. Wilfred Buckley of the urgent need for further and better investigation of the value of the familiar tuberculin tests in cattle. The Medical Research Council had previously appointed a Tuberculin Committee in 1920 to direct investigations into the methods and results of the use of tuberculin for the diagnosis and treatment of human tuberculosis, and, recognizing that the difficulties of farmers and veterinary surgeons came within the Medical Research Council's province, because of their obvious relation to medical research in tuberculosis and to the general hygiene of the milk supply, the Medical Research Council took steps to enlarge the Tuberculin Committee so as to include members of the veterinary profession and others versed in agricultural problems. This enlarged Committee set itself to inquire into the following problems:

1. It is commonly accepted that a positive reaction in cattle to the subcutaneous test implies infection with tuberculosis. In certain instances, however, in undoubted cases of tuberculosis in cattle, the reaction is either negative or doubtful. Are these discrepancies so numerous as to vitiate the general application of the test for practical purposes?
2. What are the comparative values of the different tuberculin tests—subcutaneous, intradermal, and ophthalmic?
3. What varieties of tuberculin are most efficient in the tests?
4. Can the present methods of standardizing tuberculin be improved?

On these questions the Committee has now come to some important conclusions, which are published in the Medical Research Council Special Report No. 94.<sup>1</sup>

This valuable document will help to place the whole question of tuberculin tests on a more secure footing. A great deal of the information included in its 195 pages is of a technical character, of interest only to those whose business it is to conduct these tests or appraise their value. We propose to give a brief account of the scope of the report and draw attention to its main conclusions.

The first part of the investigation made by the Committee was occupied with a study of the three tuberculin tests on eight herds of cattle—herds believed to be practically free from tuberculosis as well as those heavily infected. These investigations are reported in great detail, with temperature charts and figures of measurement. The next section contains an account of modified intradermal and ophthalmic tests employed in later investigations. This is followed by a report on the examination of veterinary tuberculin by Dr. R. A. O'Brien, and this by an abstract of a paper by Professor Dreyer and Mr. R. L. Vollon on a precipitin method for the standardization of "old" tuberculin and the expression of results in standard units. The final section is devoted to pathological evidence, and contains a report on the double intradermal tuberculin test performed on 114 cattle, the clinical results being controlled by *post-mortem* examination and biological tests. The results of this extensive research are tabulated in detail, and, commenting on it, the Committee observes that "nowhere in the available literature can be found a similar account of so extensive a series of tests followed by *post-mortem* and microscopic examinations combined with animal inoculations."

Turning to the conclusions of the Committee, we find that it metes out but faint praise to the subcutaneous method of testing. It says the subcutaneous tuberculin test appears to be a perfectly satisfactory test for the presence of tuberculosis in cattle when carried out under the laboratory conditions of a scientific trial. Under ordinary farm conditions it is not a satisfactory test; the discrepancies then prevailing are often so numerous as to vitiate the general application of the test for practical purposes. But if it hesitates over the subcutaneous tests, the Committee has found grounds for complete confidence in the intradermal test. "Of the different tuberculin tests the intradermal, as described in this report, appears to be superior to the subcutaneous tests, while the ophthalmic test should only be regarded as a subsidiary test." The percentage of error with the intradermal test is very small, in support of which statement may be mentioned that, in the Committee's experience, animals diagnosed as tuberculous by the intradermal test, though they had not shown tuberculosis on naked-eye examination, were nevertheless proved at autopsy to have been tuberculous, betrayed by microscopic examination of sections and inoculation of suspected tissue into guinea-pigs. It is fortunate that the intradermal tests have come out best in this inquiry, for they have many advantages over the subcutaneous tuberculin tests. Thus no temperature observations are required; the animal need not be kept at rest before and during the conduct of the test; interference with the ordinary farm routine is not required; only three observations are necessary; and the technique, although at first slightly more difficult than that of subcutaneous injection, is easily acquired. The variety of tuberculin recommended for the intradermal tests is "old tuberculin." It appears to be immaterial whether a bovine or human strain of tubercle bacillus is used in its manufacture. The tuberculin used must be of proved high potency, and should be administered undiluted for both the intradermal and ophthalmic tests.

The authoritative statements of this report will be welcomed by farmers and veterinary surgeons, and we hope that the conclusions with regard to the most reliable tuberculin tests will be brought without delay before the notice of medical officers of health and all other officials whose duty it is to watch over the national milk supply.

## ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

### RESUMPTION OF SITTINGS.

ON the resumption of the sittings of the Royal Commission on April 17th the Chairman (Right Hon. H. P. MACMILLAN, K.C.) alluded to the sudden death of a member of the Commission (Sir Thomas Hutchison), who was Lord Provost of Edinburgh in 1921-23. He said that Sir Thomas left behind him a record of conspicuous and varied public service.

### LUNACY LAW AND ADMINISTRATION IN SCOTLAND.

Evidence was tendered by Sir ARTHUR ROSE, chairman of the General Board of Control for Scotland, and Dr. H. C. MARR, one of the medical commissioners. The Chairman, in welcoming these witnesses, explained that the scope of the Commission's reference did not extend to Scotland, and this evidence was being received rather for the purposes of comparison with English practice than with any view to recommendations affecting Scotland.

Sir Arthur Rose stated that the Scottish Board consisted at present of five members—two whole-time medical commissioners, two members of the legal profession, who were unpaid, and himself, an honorary chairman. In addition, there were three medical deputy-commissioners, who were not members of the board, and one of these was a woman. The distinctive feature of the Scottish system was the division of the country into lunacy districts, not quite coterminous with counties, each with its local board. The law was administered under the statute of 1857; there had been various amending Acts, but no consolidating Act, as in England. The medical commissioners took it in turns to be in attendance at the offices of the board, and each of them also visited every establishment once a year, and saw every patient. Dr. Marr here remarked that these visits were not a formality; opportunity was given for making complaints, and although many of the complaints were frivolous some quite intelligent criticisms of asylum administration had been elicited from patients.

Sir Arthur Rose went on to say that the number of registered lunatics in Scotland in 1924 was 18,266 (9,112 male and 9,154 female); of these, 2,887 were private patients, and 15,379 were rate-aided. The public asylums proper consisted of the seven royal or chartered asylums, all of them philanthropic institutions, with endowments, and 21 district asylums provided by the district boards. In Scotland there was only one private asylum (at Polton, Midlothian), corresponding to what in England was called the licensed house; it contained 54 patients. There was also one parochial asylum (at Greenock), which was really a vestige of a previous system. There were lunatic wards in 14 poorhouses, with 883 patients, and there were 1,863 registered lunatics in private dwellings. With regard to the admission of patients, the sheriff's order had to be accompanied by two medical certificates for pauper and private cases alike, but the witnesses stated that even in Scotland there was a distinction between the two classes in this respect, that in the case of the private patient two medical certificates had to be given by medical men not connected with the institution, whereas in the case of the pauper patient a medical officer of the institution might give one of the certificates. Although there was no evidence that this had ever led to any abuse, it was an anomaly, and was one of the matters noted for amendment in a future amending Act.

After dealing with the procedure on discharge, the witnesses spoke of the boarding-out system in Scotland. This, Sir Arthur Rose said, was a provision for placing in suitable homes, such as small farms, a type of case which no longer required any close medical supervision, and in which country life would be beneficial. It was required in such cases that the patient should share in the family life of the people among whom he was placed, and the deputy medical commissioners were constantly in touch with these patients, even in the most remote districts of the North of Scotland.

### Observation Wards.

The witnesses were also examined on the observation wards for patients labouring under incipient forms of mental disease. Dr. Marr said, that such wards were instituted by the parish council of Glasgow in 1890. The success attending the experiment was so great that in 1904 the parish council opened, in connexion with their parochial hospital, special wards for this purpose, spacious, handsome, and admirably designed, containing 25 beds for each sex. The parish councils of Govan, Partick, and Dundee had followed the example of Glasgow. The Local Government Board (now the Scottish Board of Health) took measures for the prevention of any possible abuses or irregularities which might arise, by placing the two wards under clearly defined regulations, dealing with such questions as sufficiency of space, adequacy of medical and nursing staff, institution of registers, and duration of residence (now six

months). It was also arranged that the medical commissioner of the Board should inspect and report on these wards at regular intervals. In 1923 additional wards were arranged in the general hospital at Stobhill. Dr. Marr explained that the Stobhill Hospital, Glasgow, was a Poor Law general hospital, but in its medical administration, its staff of consultants, and its apparatus for treatment, it was on all fours with a large voluntary hospital, and in these advantages the patients in the wards allotted to mental cases shared.

### The Teaching of Psychiatry at Edinburgh.

The whole of the hearing on April 18th was occupied with the evidence of Dr. GEORGE M. ROBERTSON, professor of psychiatry in the University of Edinburgh and physician-superintendent of the Royal Edinburgh Infirmary, Morningside.

After giving an account of the Morningside institution, Professor Robertson mentioned that for forty-six years the institution had had the advantage of connexion with the University, and had founded the chair of psychiatry therein. The teaching of psychiatry at Edinburgh University consisted of thirty lectures a year, which all medical students for graduation had to attend, and the students were able to see the most important types of cases. In addition to the thirty compulsory lectures there was an optional course in medical psychology. He claimed that more tuition in this department was given at Edinburgh than at any other medical school in the world. Sir David Drummond remarked that he thought there were universities in England which gave a similar prominence to psychiatry. Professor Robertson said that the requirements in Sir George Newman's model course were less than the students at Edinburgh were receiving. With regard to facilities for post-graduate work, there was a diploma in psychiatry, and a certain number of graduates took it, but it entailed full-time work for six months, so that graduates tended to seek diplomas elsewhere, which were obtainable with more ease, but, of course, the Edinburgh diploma was correspondingly valuable.

The witness was next asked about certification in Scotland. He was of opinion that if it was made necessary for the second certificate to be given by a mental expert a good many patients would be saved from the asylum, granted, of course, that appropriate means were available for their treatment outside. Some argument ensued on the form of certificates, and the Chairman remarked that in the continuation certificate in Scotland no statement was made that the person was of unsound mind; the statement was merely that the person was likely to benefit from continued residence in an asylum. The Chairman also said that it was very desirable that certificates should be signed without any *arrière-pensée*, and should be such as the signatory could support in the witness-box if necessary. He had heard of formularies in religious matters being signed with reservations, but he did not like any reservations in medical certification.

### Insanity as a Notifiable Disease.

Professor Robertson went on to express his dissent from the procedure of judicial intervention—the sheriff's order—on the ground that he found so many patients and their friends distressed by the necessity of proceeding to the sheriff, who was associated in their minds with the apparatus of judgement upon offenders against the law. He wished all certification to be done away with, though he agreed that some substitute for the certificate must be introduced. He thought that insanity should be treated as a notifiable disease. The fact that patients, in furtherance of their medical treatment, had to be treated at a particular institution should be notified to the authorities, whose responsibility in the matter would thereby be invoked, and he believed that sufficient protection would be afforded by such notification of detention for treatment, and by the inspection of the places in which the persons were detained and the periodical visitation of the persons themselves. He agreed with Lord Russell that this would only be certification in another form, but it would be free from some of the distressing procedure at present necessary. The fact that everybody was out to evade the formalities if possible was an indication that the formalities were inappropriate.

### The Voluntary System in Scotland.

The Chairman next asked the witness for his views on the voluntary system, whereby certain patients, after a period of observation and treatment, were enabled to escape ultimate certification. Professor Robertson thought that the procedure in dealing with voluntary patients in Scotland had created something like a revolution in lunacy administration. The procedure was very simple. The patient wrote or signed a letter to the medical superintendent asking to be admitted as a voluntary patient. A letter was also sent to the Board of Control, who replied sanctioning the admission. The witness's view was that if a patient were sane enough to write such a letter he belonged properly to the category of voluntary patients. The Chairman pointed out the danger that an interested

relative might induce a patient to sign such a letter. In such a case it would be mere camouflage to describe the action as voluntary, for the patient had no power of volition. The witness said that he was aware of that danger, but the great majority of those who went in as voluntary patients appreciated their position as such, and others were quite indifferent to their surroundings so long as they were kindly treated. Forty per cent. of all private patients entered as voluntary patients. This voluntary principle was supported most decidedly by public opinion in Scotland. Indeed, there had been very little agitation in Scotland with regard to lunacy law, and there was general satisfaction with administration. Practically no cases of litigation concerning the detention of persons judged to be insane had occurred.

#### *Mental Nursing Homes.*

Professor Robertson spoke next of mental nursing homes. He had not been satisfied with the provision made for taking patients into private homes, and he took advantage of a proviso in the Scottish Act, that persons might be kept for six months in temporary residence on one medical certificate, to institute in association with Morningside and under the control of its board certain private houses for the reception of patients. The scheme had worked well; the majority of patients recovered within the six months period; in the case of those who had not recovered at the end of that time, sanction was obtained from the Board of Control for a continuation of the treatment. By some flaw in the Act there was no statutory requirement in such cases for notification to the Board of Control, although, of course, such notification was most desirable. He described these homes as part of the system of boarding out in Scotland, a description contested by Lord Russell, who pointed out that in boarded-out cases there was technically no power of detention. Mr. Micklem asked whether it was really the case that in Scotland any person might for gain take a lunatic, without a sheriff's order or the sanction of the Board of Control, and detain him for six months on one medical certificate. The witness said that that was the case, and was most anomalous, but the homes of which he was speaking, in association with Morningside, were not carried on for gain; any profits went into the funds of the institution. He would prefer all such homes to be under disinterested management.

#### *Female Nurses in Male Wards.*

The witness was next asked about the employment of female nurses in male wards. He said that in his experience such nurses had an extraordinary power of control over excited male patients, whom a male attendant might only serve to provoke. The presence of women had reduced the tendency to roughness, and had brought a new tone and atmosphere into the place. Male wards were not left entirely without male attendants, but one in each ward was generally enough. There were also certain categories of male patients for whom male attendants were advisable. But the employment of female nurses in male wards was all a part of the voluntary hospital idea which he and others in Scotland had tried to introduce into asylum administration. This was one of the ways in which the impression of an asylum as a place of detention would disappear. Another step in the same direction was the abolition of the "airing court," and, practically, of the padded room and the place of solitary confinement. Refractory patients seemed to be fewer in number in Scotland than elsewhere, and this he attributed to the enlightened ideas of treatment in vogue. For some reason there were also fewer epileptics in Scotland, the number increasing steadily as one came southward. In his own institution a certain number of wards had no locked doors at all, and no patient at Morningside was ever locked in solitary confinement. A member of the Commission asked what was done in the case of the violent patient knocking his head against the wall. Professor Robertson said that he had rarely seen the patient who gave way to continual violence; he had seen such manifestations, lasting perhaps only five minutes. On the general subject of restraint he said that a hundred years ago the large measure of restraint employed in asylum administration was mainly due to the fact that only one attendant was assigned to thirty or fifty patients. With the increase in the number of the staff the apparatus of restraint was largely abolished, with the result that the patients became more and more quiet. There was no doubt that the better treatment now given in acute manias as compared with the past was the chief reason why this disease appeared to be of a milder type than formerly. Excitement, noise, and violence among the inmates of an institution had greatly diminished. With regard to chemical restraint, he would not object to hyoscine, which was exceedingly valuable in an emergency, but should never be used continuously. He believed greatly in the effect of baths and rest in bed for patients who were inclined to be excited. The failure of doctors and nurses alike in the past was in regarding excitement in a patient as merely a symptom of the disease, to be treated by physical restraint or drugs or in any way that

offered. After observation he had come to the conclusion that a great many of these cases of excitement were due to some easily ascertainable form of irritation, and if trouble were taken to find out the cause and to remove it the patient's excitement would disappear. He recalled a case in a private house in which three or four nurses were holding down a struggling patient. His assistant found on inquiry that the patient had the idea that the gas taps were turned on and that an explosion was imminent. He told her that he would see to the matter; he examined the taps, and on his return reassured her, and she immediately became quiet, as she would never have done, short of exhaustion, along the lines which the nurses were pursuing. Insane persons, while their thinking often proceeded from false premises, were quite capable of logical reasoning, and their actions were those of a normal person on such reasoning. It was well to take trouble to discover their reasoning processes; otherwise treatment by restraint, without sympathetic study of insanity, might exasperate rather than cure.

#### *Early Mental Wards in a General Hospital.*

On April 20th the first witness was Dr. JOHN D. COMRIE, senior assistant physician, Royal Infirmary, Edinburgh, who described the early mental wards, of which he is in charge, at that institution. In part his evidence repeated the statements made in his article in the *BRITISH MEDICAL JOURNAL* of September 27th, 1924 (p. 551), reprints of which were distributed to the members of the Commission.

Dr. Comrie mentioned that as far back as 1738, shortly after the hospital received its charter, it was recorded in the minutes that "as there is no proper place in Scotland for entertaining lunatics the managers propose to prepare in this part of the house to be built five cells to entertain such lunatics whose expenses their friends will defray." The present mental wards, very different from the cells there suggested, were two in number, one of 16 beds for male patients, and the other of 8 beds for female patients, with the possibility of two additional beds in either case. Asked what extension he would make if he were given a free hand, he said that he thought that 50 beds would serve the needs of Edinburgh and district. More accommodation was desirable in order that cases might be classified and noisy patients segregated. He himself visited the wards every day and saw every patient. A resident medical officer was also in attendance, but the duty of this officer included supervision of another ward as well; there was, further, a non-resident doctor who acted as clinical assistant. The nursing staff included, in addition to the sister in charge, eight female nurses and three male attendants, who were called "porters," and whose status was below that of nurses. It was at all times possible to bring in special nurses from other wards of the hospital as required. Cases were sent to these mental wards by outside doctors, a certain number came through the out-patient department of the hospital, and cases which had been treated in other wards were transferred to the mental wards on mental derangement supervening on the physical ailment. No certified cases came in; the patients were all voluntary, at all events in the same sense as patients in a general hospital, and, theoretically, they could go out at any time. In practice restraint was exercised, if necessary, in the patient's interest, in the same way as, say, in a delirious fever case, and surgical restraint (bandages) was used in the case of a patient who was inclined, say, to remove the splints from an injured leg. The wards acted as a kind of clearing house, and large numbers of patients were saved from certification. An advantage of such wards being in a general hospital was the ease with which physical conditions—infective, exhaustive, or reflex—operating as partial causes for the mental condition could be discovered and dealt with in a large proportion of the cases of confusional mental states, melancholia, and psychoneuroses. The association of mental cases with patients who were normal mentally and the greater freedom of access by the public to a general hospital than to an asylum were also important factors in expediting the recovery of the patient and establishing public confidence. The wards, in fact, took, for rate-aided patients, the place of the voluntary nursing homes available for paying patients. Dr. Comrie furnished a number of figures giving results; it appeared that about 60 per cent. of these slighter and undiagnosed cases of mental disorder might be expected to recover sufficiently to return home within a period of six weeks. In 50 per cent. of the psychoneuroses and hysteria cases with very marked mental symptoms a definite physical cause was discovered. The manic-depressive cases did not respond so well to the treatment given as did others. In reply to questions about the diminution of cases due to alcohol, Dr. Comrie said that he attributed this to the lessened consumption of alcohol in Scotland; this in its turn was due to economic reasons (lack of employment). The cases of delirium tremens showed a marked reduction. In general, the severity of such alcoholic cases as came in was not nearly so great as formerly.

*Provision for Incipient Cases by Local Authorities.*

The second witness was Dr. JOHN CARSWELL, who had been certifying physician in lunacy for Glasgow from 1889 to 1914, and commissioner of the Board of Control for Scotland for a number of years.

Dr. Carswell gave an account of his pioneer work in Glasgow in connexion with the treatment of incipient cases of insanity. This work started in 1889, when he suggested to the local authority that arrangements should be made for the treatment of such cases. At that time there was no systematized knowledge or study of mental disorder until patients arrived as certified lunatics at the door of the asylum, and no provision then existed anywhere for meeting the needs of such patients in the early stages of their derangement. The result was the setting up of observation wards in the hospitals of the local authority, as already described in the evidence of Sir Arthur Rose and Dr. Marr. Here cases could be sorted out before certification. The work called for great responsibility in the physician, who must keep himself informed of the views of the lunacy authorities, and must be aware of the legal pitfalls; but of the many thousands of cases which passed through his hands while he held the office in Glasgow the parish council was not required to answer a single letter of complaint. Asked whether such a scheme would not prove very difficult for rural districts, Dr. Carswell said that he did not think the difficulty was as great as was commonly supposed. In Southern England, at all events, in comparison with the conditions in Scotland, the means of communication between outlying villages and small towns were very good, and the transfer of patients from rural places to centres in which hospitals were situated should not be difficult. He emphasized very strongly the need that every person alleged to be insane or mentally deranged should be visited in his own home, if at all possible, by a special medical officer. It was very important that the patient's home surroundings as well as his actual state of mind should be investigated. The arrangement in Glasgow when he was in charge there was that, on a medical man becoming aware of such an illness in an artisan family, he reported the case to the inspector of the poor, who was under obligation immediately to communicate with him (the witness), and he at once visited the patient. It was within his discretion to send the patient to the observation wards or to remove him direct to the asylum. Persons who were homeless and had perhaps attempted suicide or shown other signs of mental disorder were notified to him by the police, and he made an examination of them in the police office. In such cases there were no court proceedings, though "disorderly conduct" might be entered on the charge sheet. He found the hospital associations and atmosphere of the observation wards conducive to recovery. More than half the cases thus treated for mental disturbance escaped ultimate certification. Under this system the sorting out of cases was done twice—originally in the visit to the homes of the patients immediately on notification, and again after they had been a short period in the institution. In reply to Mrs. Mathews, who asked whether there were any means of avoiding the intervention of the inspector of the poor, the witness replied that his own view was that the proper authority for receiving such intimations was the health authority, and on the suggestion of Sir Humphry Rolleston he promised to submit to the Commission a memorandum elaborating his view that the health authority should take the place of the Poor Law authority in this respect.

The Commission adjourned until a date in May to be announced.

## Canada.

[FROM OUR OWN CORRESPONDENT.]

### PUBLIC SUPPORT FOR MEDICAL RESEARCH.

It is a welcome sign of the times that the laity is becoming alive to the benefits to be derived from concentrated study of the elusive problems of certain diseases. The medical research committee of the University of Manitoba, Winnipeg, has recently received a gift of two thousand dollars apiece from eight business men of that city. At the laboratories of the medical college investigations upon the chemistry of the blood will be supported by these funds, and at the general hospital certain blood diseases, especially pernicious anaemia and the leukaemias, will be studied. The research committee hopes to link this fund up with the Gordon Bell Memorial Fund which was established last October, when twenty thousand dollars were set aside.

### IODINE AS A PROPHYLACTIC OF GOITRE.

Goitre has for some time been very prevalent amongst animals and human beings in the Pemberton Meadows district of British Columbia. Dr. W. D. Keith, who undertook to investigate the subject, published a report on his investigations in the *Journal of the Canadian Medical Association* a year or so ago. The results of feeding iodine to cattle were very gratifying. Mr. John Ronayne of this district carried out the experiment and has shown that the total cost of the iodine required for one hundred head of cattle, twelve horses, two hundred chickens, and a number of other domestic animals was only two dollars a year.

### CONFERENCE ON MEDICAL SERVICES.

A conference on the medical services in Canada, arranged by the Canadian Medical Association, with the approval of the Hon. Henri Beland, Minister of Health for Canada, was held in the House of Commons, Ottawa, last December. A report of the papers read and of the discussions they provoked is published in the March issue of the *Journal of the Canadian Medical Association*. The chairman of the conference was Dr. Alexander Primrose, C.B., of Toronto University.

### Medical Licensing in Canada.

Among the subjects dealt with was that of "Medical licensure in Canada." This has been a very knotty problem for many years. In Canada the licensing of medical men is a function of each individual province, and time was when practically no reciprocity existed amongst the provinces. Through the determined effort of the late Sir Thomas Roddick, M.D., an Act was passed in the Dominion House creating a Medical Council of Canada in 1912; it was a step in advance, but still conditions are not entirely satisfactory. At the present time the young man who has obtained his medical degree in Canada has a choice of two methods of obtaining his licence. He may sit for the professional examinations of the province in which he wishes to practise, as the greater number of graduates still continue to do; or he may, upon presentation of an "enabling certificate" from the registrar of any province that he has fulfilled all the requirements of that province as to preliminary and medical education, sit for the examinations of the Medical Council of Canada. In the first case he can register only in the province in which he was examined; in the second he is nominally entitled to licence in any province. Actually, however, only eight of the nine Canadian provinces fully accept the examinations of the Dominion Council (as it is loosely called). Quebec, ever jealous of its rights and privileges, maintains that the Dominion examinations may properly be taken only after all provincial conditions for licensure have been fulfilled, and refuses to give an "enabling certificate" to the graduate of any medical school in the province of Quebec unless he has (1) fulfilled all of the provincial requirements as to preliminary education, (2) been on the provincial register as a medical student for five years, and (3) passed all of the provincial licensing examinations, which extend over a period of five years. Furthermore, graduates of these schools who belong to other provinces where they have registered and who wish to obtain a licence in Quebec by reciprocity, are allowed to do so only when they have passed the examinations of the Medical Council of Canada, after having previously passed the professional examinations of their own province. In contrast to Quebec, British Columbia has abolished its own provincial examinations, and grants licence only to those graduates who have passed the Dominion Council. Were all of the provinces to adopt this procedure the difficulties of Canadian licensure would pass away. There is still another way of obtaining a licence to practise in a province of Canada, for all the provinces, except British Columbia, have, since the war, entered into reciprocity with the General Medical Council of Great Britain. The prospective licentiate can enter into the promised land by a circuitous route. He can avoid the examination of the Dominion Medical Council by sending to Great Britain his certificate of provincial registration,

## New South Wales.

[FROM OUR OWN CORRESPONDENT.]

PROFESSOR JOHN IRVINE HUNTER.

THE members of the New South Wales Branch of the British Medical Association met at the British Medical Association Building, Elizabeth Street, Sydney, on December 18th, 1924, to pay homage to the memory of John Irvine Hunter. Dr. Andrew Davidson, President of the Branch, said: "We have met this evening so that we may place on record our deep sense of loss in the untimely death of Professor John Irvine Hunter. He was a great scientist. His industry was invincible. He was a great power to put anatomy on a sure foundation, and thus gave to the study of surgery and of pathology their true place. He loved his work, and in his incessant industry laboured as if life were too short (as it proved to be) for the work he had to do. His life was a sacrifice to science. 'Out of his work, out of his discoveries came, and will come, health and safety and length of days and delivery from pain.' His earnest aim and intense and beautiful character made him to all of us a guide, philosopher, and friend." Professor A. E. Mills (Dean of the Faculty of Medicine, University of Sydney), Professor F. P. Sanders (Professor of Surgery), and Dr. F. A. Maguire (acting Professor of Anatomy) all spoke, and a letter was read from Dr. J. W. Dunbar Hooper, the President of the Victorian Branch.

DR. SYDNEY JAMIESON.

Dr. Sydney Jamieson, who had been associated for many years with the work of the Sydney University and the Sydney Hospital, died on January 25th. A disorder of the heart had troubled him during the last six months, but he continued to attend his patients until two days before his death. Dr. Jamieson was born in London sixty years ago. With his people—his mother is still alive—his first home overseas was in Tasmania, but he received most of his early education in Sydney, where he received the Sydney Grammar School, the Hurlstone College, and graduated in arts at the University of Sydney. With a reputation as a footballer and cricketer, he went to Scotland in 1884, and four years later took the degrees of M.B., M.Ch. in Edinburgh. On his return to Sydney, in 1891, he was appointed assistant physician at the Sydney Hospital, and gradually advanced through various stages of the honorary staff until, when he retired about 1918, he had completed twenty-eight years' service. He established at the hospital the department of pathology, which has now become a most important adjunct. He had acted for a period as demonstrator of pathology under the late Professor Greenfield in Edinburgh.

WELFARE OF MOTHERS AND BABIES.

The success of the work of the Royal Society for the Welfare of Mothers and Babies has rendered the extension of the Mothercraft Centre at Petersham imperative, and additions have been made at a cost of £1,000. The new wing was opened by the Minister for Health on December 6th, 1924. In the last three years, since the inception of the work, the institution has treated 5,100 out-patients and babies and 700 in-patients. About 160 nurses have been trained for this class of work; among them are the matron of the King Edward Hospital, Perth, and the matron of the Adelaide Baby Clinic Health Centre. The Government of New South Wales has made it a condition that all nurses employed in the State baby health centres must have the additional qualification of a post-graduate training at the society's institution. The baby welfare centres at Woolloomooloo and at Surrey Hills are doing excellent work, and the free distribution of milk from these centres has had an excellent effect upon the children. The forty-eight health centres now in operation cost the Government £22,000 a year. The Country Women's Association and the Bush Nursing Association are co-operating in the movement, and at the request of the Bush Nursing Association Bush nurses will be trained free of cost.

together with a fee, and obtain British registration and then register in any province. There are, however, four exceptions: (1) British Columbia, as stated above; (2) Saskatchewan, where the Medical Act has been changed so that it grants medical registration only to those registered by passing the examinations of the General Medical Council of Great Britain—query, is there such an examination? (3) New Brunswick, which does not allow reciprocity with Great Britain unless proof be given of bona-fide residence in that country by those possessed of a certificate of British registration; and (4) Quebec, which will not grant reciprocity through Great Britain to the graduate of any medical school within its province. The question produced a lively and very interesting discussion at the conference.

Public Health and Medical Education.

Dr. John W. S. McCullough, Chief Officer of Health for Ontario, in his address, "The greatest public health need of Canada," pleaded for full-time local health officers; in this country, outside the large cities, there is no completely satisfactory organization for carrying on public health work in an efficient and economical way. The need was much felt last year in one district of Ontario during a small-pox outbreak. In British Columbia the provincial medical association has been investigating the question of health insurance, facts about illness amongst workmen have been collected, and statistics of accidents have been drawn up. Dr. J. H. MacDermot of Vancouver outlined in his paper what had been done, and stated: "We in British Columbia do not think that the medical profession should strive to inaugurate any scheme, but that we should educate ourselves thoroughly with regard to all its advantages and disadvantages and remain receptive, but ready to meet any situation that may arise." The physicians of British Columbia are educating themselves for any eventuality such as a proposal of the Provincial Government to draw up a plan for general health insurance. Perhaps the topic in which the greatest interest was shown at the conference was medical education. Never before, probably, was there so much talking about this subject as there has been in recent years in Canada and the United States, and it is still going on. Professor J. J. R. Macleod, of the University of Toronto, and Dr. C. F. Martin, Dean of the Faculty of Medicine, McGill University, read good papers on the subject. In Toronto certain optional courses may be taken by the medical student. It was the general feeling of the conference that a certain minimum amount of time must be allotted for each subject, yet the curricula of all the medical schools should not be exactly the same, and each medical school should be allowed scope to develop its own individuality. It was also felt that the student must not be "stuffed" during every hour of the day, but should be left some time to think.

If one who has seen something of medical education on both sides of the Atlantic be allowed to express an opinion, I should say that in Canada the medical student does not show that he has had as good a general education from his earliest years up as does the English student. Dr. J. C. Connell, Dean of the Medical Faculty, Queen's University, Kingston, felt that some of the medical schools of Canada had not been quite fairly dealt with by the Council on Medical Education of the American Medical Association in their classification of medical schools. Apparently, in one instance, on the issue of a second report a school was retained in "Class B" without a reinspection having been carried out.

TRAINING OF PUBLIC HEALTH NURSES.

The University of Montreal has instituted a post-graduate course for the training of public health nurses. The school is to receive financial aid from the province of Quebec and also from the city of Montreal. All nurses on the city's staff are to receive training free of charge. The civic authorities have placed two of the most populous parishes, St. Catherine's and St. James's, at the disposal of the school. Here the problems of infantile mortality, tuberculosis, children's diseases, and maternity, and of hygienic conditions generally, will be closely studied, and annual reports will be drawn up to demonstrate to these districts the value of properly guided public health nursing.

**NURSES' REGISTRATION ACT OF NEW SOUTH WALES.**

This Act, which recently received Royal assent, provides for the registration of general, mental, and obstetric nurses; it prescribes a period of training of not less than three years for the two former and of six months for the latter. The constitution of the Nurses' Registration Board is:

- The Director-General of Public Health.
- The Inspector-General of Mental Hospitals.
- The principal teacher of obstetrics in the University of Sydney.
- One legally qualified medical practitioner, who shall be nominated by the New South Wales Council of the Australasian Trained Nurses' Association.
- Three nurses, two of whom shall be nominated by the New South Wales Council of the Australasian Trained Nurses' Association.

**A ROYAL COMMISSION ON NATIONAL HEALTH.**

A Royal Commission on National Health has been appointed, consisting of Sir George Syme, K.B.E., M.S., F.R.C.S., Dr. Frank S. Hone, Dr. R. H. Todd, Dr. Jane Stocks Greig, and the Hon. S. R. Innes-Noad, M.L.C. It is instructed to inquire into the following matters:

- (a) The co-ordination of medical services of Commonwealth departments in regard to all matters affecting public health.
- (b) The co-operation of Commonwealth and State health authorities.
- (c) The prevention of the outbreak, development, or spread of disease in the Commonwealth.
- (d) The prevention of venereal disease and the exercise of control and the treatment of persons suffering from venereal disease.
- (e) Uniform legislation with regard to purity of food and drugs.
- (f) Maternity hygiene and child welfare.
- (g) Industrial hygiene.
- (h) The encouragement and development of research work.
- (i) The relationship which should exist between public health authorities and other public authorities rendering medical services.
- (j) The relationship which should exist between public health authorities and medical practitioners in regard to the prevention of disease.
- (k) The publication of information relating to matters concerning public health.

**India.**

---

**GRANT MEDICAL COLLEGE, BOMBAY.**

On March 16th the Governor of Bombay unveiled at the Grant Medical College a portrait of Sir Temulji Nariman, one of the oldest medical practitioners in Bombay, who has taken a very keen interest in the growth and extension of the College, with which he has for many years been closely associated. He was educated at the College and at Edinburgh, obtaining the diplomas L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glas., and L.M. in 1895. In 1899 he was vice-president of the Bombay Medical Congress, and received the Kaiser-i-Hind gold medal. In 1922 he obtained the honorary diploma of M.R.C.P. Edin., and was President of the College of Physicians and Surgeons at Bombay in 1923. He is honorary physician to the Parsee Lying-in Hospital, and examiner in midwifery and diseases of women in Bombay University, and a justice of the peace for Bombay. He received the honour of knighthood in 1914. The Governor paid a tribute to the Bombay municipality for the assistance rendered to the College in enlarging the scope of training in midwifery. He expressed surprise that up to the present no dental hospital or centre for teaching dentistry had been founded as part of the College.

**KASHMIR MEDICAL MISSION.**

During 1924 the pressure of work at the Church Missionary Society's Hospital in Srinagar, Kashmir, continued undiminished; there were 18,762 new out-patients and 1,994 in-patients, and 5,501 operations were performed. The new x-ray outfit, towards the cost of which the Countess of Reading contributed generously, has been of particular value. The financial position is less satisfactory than in previous years, partly owing to the loss of income due to the new Kashmir State arrangement, by which a directorship of medical services has been created and a whole-time residency surgeon appointed to Srinagar. It was necessary to withdraw money from invested funds in order to balance expenditure. The hospital serves a population of some three

and a half millions, and, since Kashmir is on the main line of communications to Central Asia and Tibet, representatives of many frontier tribes are frequently passing through. The Leper Hospital in connexion with the mission was built in 1891, on a peninsula jutting into the Dal Lake, and during the last year received 215 in-patients, 147 surgical operations were performed, and 187 injections of ethyl esters given; the more serious surgical operations were performed in the Mission Hospital. A new children's home is being erected, a grant of Rs. 25,000 having been sanctioned; it will consist of a central house for the nursing superintendent, and two wings, one for boys and one for girls.

**MEDICAL TREATMENT IN BOMBAY VILLAGES.**

The Bombay Government is endeavouring to provide some form of medical relief for the people in the smaller villages in the Presidency, comprising a population of six millions. In the smaller villages, where it would be financially impossible for a medical practitioner to settle, the Government intends to train village schoolmasters in the rudiments of medicine and surgery. Experimental schools have been opened already in Poona and Bijapur, five schoolmasters receiving elementary instruction in each place. The training is to last for two and a half months, and the schoolmasters will then be paid 10 rupees monthly for the whole of the village health. A second scheme is contemplated which will induce medical practitioners to settle in the smaller towns and larger villages, by offering a bonus for the initial settlement and also a monthly allowance.

**Scotland.**

---

**EDINBURGH CAMPAIGN AGAINST DIPHTHERIA.**

In a lecture on the prevention of diphtheria given by Dr. M. T. Benson, assistant medical officer of health, Edinburgh, under the auspices of the Leith Parents' Association, he described the preventive work carried out among Edinburgh school children during the course of the last year. Twenty-six schools were visited, and the public health authority had given to the parents of over 11,000 school children under 10 years of age the opportunity of having their children examined by the Schick test, and, if found necessary, subsequently immunized against diphtheria. The percentage of parents consenting had ranged from 11 to 85 at different schools. In the aggregate the Schick test was applied to some 4,500 children; almost 3,000 were found to be susceptible to diphtheria, or roughly 65 out of every 100 school children between 5 and 10 years of age. Of children between 1 and 5 years of age who were tested, 80 per cent. on an average were found to be susceptible to the disease, and in certain groups of children under 5 years of age as many as 95 per cent. This early age was the time at which the great majority of children were apt to contract diphtheria if brought in contact with it, and this also was the age at which diphtheria, if it was contracted, was most dangerous; more than 60 per cent. of the total deaths from diphtheria in Edinburgh occurred in children under 5. In performing the test three injections of a special toxin-antitoxin mixture were given under the skin of the arm at intervals of a week. Though three injections were necessary, they did not upset young children, and Dr. Benson had not seen an instance of a protective injection followed by any unduly severe or permanent ill effects, after personal experience of over 10,000 injections in Edinburgh. In one school 430 children between 1 and 11 years of age had been treated from January to May, 1924, and in the subsequent period of fourteen months one case of diphtheria had occurred in a highly susceptible child, who, it was noted, did not develop protection after the ordinary course of three toxin-antitoxin injections, and an extra protective injection had been given. The attack was extremely mild, and he thought this good result could be reasonably credited to the protective treatment the child had undergone. In some 120 children under 11 years of age at the same school who had not been treated, no fewer than

ive cases of diphtheria, of which three had been very severe, occurred during the same period of fourteen months. According to this proportion eighteen cases might have been expected among the 430 treated children, instead of the one very mild case which had actually developed. He suggested, therefore, that children should be protected as soon as possible after they were 9 months old. Dr. William Robertson, M.O.H. for Edinburgh, said that the Public Health Department of the city of Edinburgh might take credit for having pioneered the system of protection against diphtheria in this country, and he desired to thank the Leith Parents' Association for the enlightened and intelligent support given to the movement. He was satisfied that diphtheria could be prevented if children were treated with doses of toxin-antitoxin, and for that reason he asked for the further co-operation of the public.

#### STUDENTS' HELP FOR SCOTTISH HOSPITALS.

The students of St. Andrews University on April 11th made a special effort to help the funds of Dundee Royal Infirmary by organizing a fancy dress parade in the university town. As the result they were able to hand over to the hospital about £400. On the same day Glasgow students held a students' day at Ayr on behalf of the Ayr County Hospital. Earlier in the week a concert had been held in the Town Hall and a magazine had been sold in the streets; £500 was realized on behalf of the hospital, of which £200 was collected in coppers. On the same day also a students' day was held at Kilmarnock on behalf of Kilmarnock Infirmary, the methods adopted being very much the same as those adopted at St. Andrews and Ayr, with a fancy dress carnival held in the evening in the Agricultural Hall, attended by over 1,000 persons. The total amount realized at Kilmarnock was over £630.

#### LETTERS OF MARY QUEEN OF SCOTS.

In the JOURNAL of November 22nd, 1924, it was mentioned that a sum of £2,250 was necessary to secure for the Scottish National Library an important series of thirty letters and papers connected with Mary Queen of Scots, and that a fund had been opened under the patronage of the Duchess of York for their purchase. A sum of only £120 is now required to complete the purchase price. The letters will form a valuable addition to the many important documents already in the possession of the Scottish National Library dealing with this subject. Subscriptions may be sent to Dr. C. Stewart Black, 93, High Street, Paisley.

## Ireland.

#### IRISH MEDICAL COMMITTEE.

A MEETING of the Irish Medical Committee, held in the Royal College of Surgeons, Dublin, under the chairmanship of Dr. Joseph Power, was attended by Drs. J. M. Day, M. R. J. Hayes, J. T. Elliott, J. C. King, W. W. Murphy, H. G. Roche-Kelly, J. O'Meara, E. T. King, C. Eccles, D. Morrissey, D. H. Donovan, Mary S. P. C. J. Shanley, J. H. Counihan, R. J. Quire, T. J. Farrell, A. D. Courtney, Secretary), and C. H. Gick (Secretary).

Apologies were received from Senator W. O'Sullivan, M.D., Drs. T. B. Costello, H. T. Warnock, and H. Raftery. **Medical Registration.**—A letter was read from the secretary of the Ministry of Local Government inviting the Irish Medical Committee to nominate three delegates who, with representatives of the medical licensing bodies, were requested to meet the Minister in a conference with regard to arrangements for the future control of the medical profession in the Free State. Drs. Power, Rowlette, and Hennessy were selected to represent the Irish Medical Committee, and were instructed to urge the continuance of the existing arrangements for medical registration. In the absence of Dr. Power, Dr. M. R. J. Hayes was appointed substitute. Resolutions were read from the

Undergraduates' Association in the University Colleges of Cork and Galway requesting that the Committee should oppose any change in the existing system of medical registration in the Free State.

**Motor Car Taxation.**—It was proposed that the tax should be on petrol, subject to 50 per cent. reduction for medical practitioners. An amendment that the tax be upon horse-power, subject to 50 per cent. reduction for medical practitioners, was lost by 6 to 8, and the original proposition carried by 8 to 6.

**Registration of Births, Deaths, and Marriages.**—Arising out of a discussion with regard to the new quarterly Form S in connexion with births, deaths, and marriages, it was unanimously resolved:

That we consider the new quarterly Form S, issued by the Registrar-General, as entailing a great deal of additional work, and, in view of the already inadequate remuneration, we request the Registrar-General to take the necessary legislative steps to have the fees for the registration of births, deaths, and marriages increased to three shillings for each entry.

**Scales of Medical Salaries.**—The refusal of the County Mayo Board of Health to accede to the request of the Minister of Local Government and Public Health to fix a scale of salaries for its medical officials was discussed at length, and it was resolved:

That the Minister of Local Government and Public Health be requested to exercise his powers to fix a scale of salaries for the County Mayo medical officers at the same rate as exists in the County Galway.

**Temporary Duty.**—Owing to the frequent disputes arising in connexion with remuneration for holiday duty, resulting in medical officers being deprived, in many instances, of their annual holidays, the Committee requested that the Minister of Local Government and Public Health should fix the remuneration as follows:

(a) For dispensaries £7 7s. a week, (b) for district and county hospitals a minimum of £5 5s. a week, and, in all cases, not at a less weekly rate than the yearly salary.

**County Hospitals.**—With regard to county hospitals, the following resolutions were passed: (a) That the minimal salary for a county hospital surgeon be £1,000 per annum; (b) that the county surgeon should be permitted to engage in consultative practice only; (c) that in both county and district hospitals patients only for whom the State is statutorily responsible should be admitted for treatment; (d) that if private patients are admitted they should be treated in a hospital apart from those entitled to treatment by the State, and that their private medical attendants should have the right to attend such patients with the county surgeon.

**Salaries of Whole-time Medical Officers.**—The Committee resolved that the salaries of county medical officers of health, tuberculosis medical officers, and medical inspectors of schools should be on the scales adopted by the British Medical Association for Great Britain, and that where lower salaries are offered the medical journals be requested not to advertise the posts.

**Committee on Reform of Medical Services.**—The Committee expressed its disappointment at the delay in publishing the interim report of the Committee of Inquiry into the reform of medical services, especially in view of the unsatisfactory condition of the medical services in the Free State and the temporary arrangements made for the medical certification of sickness benefits under the Insurance Act.

**Amalgamation of Dispensary Districts.**—The Committee expressed a strong opinion that the population of the dispensary districts in Cork City are already too big for efficient medical attendance on the sick poor, and, in the circumstances, condemned the proposals for their further increase by amalgamation.

**Medical Members of Dail and Northern Parliament.**—The Committee resolved unanimously as follows:

That Dr. R. J. Johnstone (Chairman, Irish Medical Committee) and Dr. Hugh Morrison be congratulated on their election to the Northern Parliament, and Dr. T. Hennessy (Irish Medical Secretary) on his election to the Dail.

## England and Wales.

### BEDFORD COUNTY HOSPITAL.

At the annual meeting of the Bedford County Hospital Guild on April 7th the possibility of providing a maternity department in the hospital was discussed; such a department would include a pre-natal clinic, observation, isolation, and lying-in wards, and an operating theatre. An address was given by Dame Janet Campbell, M.D., senior medical officer at the Ministry of Health for maternity and child welfare work, who dwelt on the need of better hospital facilities for maternity cases. Local authorities had already established about 120 maternity homes, chiefly in adapted buildings, but it would not be satisfactory for a new welfare service to develop out of connexion with the ordinary established hospitals. The Ministry always preferred to work in conjunction with such hospitals, and financial grants were obtainable. In the course of the meeting it was announced that the Bedford County Hospital Guild had already raised a sum approaching £2,000 in aid of the hospital. It had given active support to the work of providing a convalescent home and paying wards, and was at present concerned in helping to furnish the new nurses' home. The balance sheet showed that the house-to-house collection in Bedford during the past year had resulted in a sum of £618 being raised—£14 more than in the previous year.

### RICKETS AND TEETH DEFECTS IN SHEFFIELD.

A lecture was given on March 26th in the University of Sheffield, on the invitation of the Sheffield Local Medical and Panel Committees, by Professor E. Mellanby, F.R.S., on "Can rickets and defective teeth be eliminated from Sheffield?" At the outset the lecturer pointed out his pleasure in giving some account of the work, and result of the work, carried out at the university field laboratory, for whose establishment the panel doctors of the district were partially responsible. He then described by means of lantern slides the experimental work on animals whereby the antirachitic and the rickets-producing effects respectively of different foodstuffs had been determined. It was shown that the antirachitic foodstuffs were rich in vitamin A, and that in fact this action depended largely on the presence of an antirachitic vitamin, which had many properties and a distribution very similar to vitamin A. Cod-liver and fish oils, milk, suet, butter, eggs, and cheese were antirachitic, especially the first of these. The antirachitic effect of butter was enhanced by the presence of calcium salts. He referred also to Huldshinsky's work, and showed that the ultra-violet light need not necessarily be applied to the skin, but that its direct application to some foodstuffs increased their antirachitic effect. Thus, the antirachitic action of milk was increased by exposure to a mercury-vapour lamp.<sup>1</sup> The rickets-producing effect of cereals, most potently seen in the case of oatmeal, could be antagonized either by antirachitic vitamin in the diet or to a less extent by exposure of the animal or the oatmeal to the ultra-violet rays. Much of the lecture was occupied in giving an account of Mrs. Mellanby's work on the dietetic and other conditions which control the formation of perfect and imperfect teeth. Her work showing the relation between the formation of children's teeth and their susceptibility to caries was also described; also the investigations, undertaken with the co-operation of C. Lee Patterson and W. Proud, in which it was shown that the incidence and rate of development of caries in children could be controlled by altering their diet, were described. Professor Mellanby urged the medical men present to make use of the facts experimentally demonstrated in the feeding of children, and endeavour thereby to eliminate the appalling condition of dental and bone defect, so extensively found in this country. At the close of the lecture there was an interesting discussion, in which Drs. Mackinnon, A. E. Naish, Turner, A. E. Barnes, R. Hallam,

and others took part. Professor Mellanby, in his reply, stated the superiority of a good 50 per cent. emulsion of cod-liver oil over oil and malt, which usually contains about 10 per cent. oil. Oatmeal when taken with abundant milk or with fat fish could give excellent results, but oatmeal without such substances was detrimental. Dr. Forbes in a happy speech proposed a vote of thanks to the lecturer, and this was seconded by Dr. Lucy Naish.

### BIRMINGHAM EXHIBITS AT WEMBLEY.

Three scale models at the Wembley Exhibition this year will illustrate the latest developments of the treatment of tuberculosis in Birmingham. One model represents the artificial light treatment block at Yardley Road Sanatorium; a second, one of the open-air wards in the same institution; and the third, one of the open-air classrooms at Uffculme. The first model, which measures 5 ft. by 4 ft., shows two treatment and subsidiary rooms, including a power house with a working model of a dynamo; each room in the model is electrically illuminated. The models have been constructed by Mr. Raymond T. Cooke, the manager of the public health departments works, to the scale of one inch to the foot, and are complete in detail.

## Correspondence.

### WHAT IS AN EYE SPECIALIST?

SIR,—I am much obliged to you for the very friendly notice of my pamphlet entitled *What is an Eye Specialist? or the General Medical Council and Ophthalmology*, which appeared in your issue for March 28th (p. 618). Perhaps you will allow me just to make one or two observations. I admit at once that your article is a very fair one except on one point, and that is as to the responsibility of the General Medical Council. It seems to be assumed in your article that the General Medical Council is in no way responsible and that the responsibility rests on the Government. Are we to understand from that that if the General Medical Council finds something wrong, it feels precluded from approaching the politicians with the view of giving them advice? Was the General Medical Council too supine, or did it refrain simply because it was afraid that the statesmen and politicians would pay no attention to it? Are we also to understand that when statesmen contemplate new legislation about medical matters they think so little of the General Medical Council that they do not ask its opinion? Did the statesmen, of their own accord, insist upon diplomas in public health and special diplomas in dentistry, or were they approached to do so by the General Medical Council or other medical authority?

Now as regards the very favourable view of school testing taken in the article. I regret extremely that I cannot just see eye to eye. Are the eyes of all the children in the schools examined by the ophthalmometer and under a mydriatic? Without such precautions the examination of the eyes of young children is of very little value. I have known children pass a so-called eye examination at school with hypermetropia ranging from 4 to 6 dioptres. My own case, quoted in the pamphlet, would have passed as all right, for I had 6/6 vision, and yet I have 2 dioptres of hypermetropia and nearly the same amount of astigmatism. Up to the age of 24 I had still 6/6 without glasses, but only read with very great trouble. The rough testing of the children in some schools with which I am acquainted is done by the teachers at the rate of 150 children to the hour. Only those who come down in this perfunctory examination are referred to special practitioners.

As an example of what may happen: a patient at a well known eye hospital got a prescription, spherical +0.75 for each eye. The real reading was, in one eye spherical +2 cylinder +2.5 axis horizontal; in the other eye it was spherical +2, cylinder +1.5 axis horizontal, and the prescription of +0.75 for a case like that was initiated by a full surgeon to that hospital, and a gentleman who is generally looked upon as an authority on school eye testing. I have no wish to repeat the argument of my pamphlet.

<sup>1</sup> See S. J. Cowell: Irradiation of Milk and the Healing of Rickets. *British Medical Journal*, March 28th, 1925 (p. 594). See also Cereals as a Factor in Rickets, *British Medical Journal*, April 11th, 1925 (p. 724).

It is now on the market and copies can easily be obtained, but I think my contention is not wrong that if public money is going to be spent in large amount on eye testing, then every precaution should be taken that the persons who receive this money give value for it, and that in optical work they have the same thorough training that opticians have. That a certain number of persons practising as eye specialists practise without such a training is entirely the fault of the General Medical Council. I have no desire to hinder anybody practising ophthalmology if they wish, but when they are going to be paid by the State then ample means should be taken to see that they are value for the money spent upon them.

Again thanking you for the courtesy of your article.—I am, etc.,

Glasgow, April 14th.

ANDREW FREELAND FERGUS.

### TREATMENT OF DIABETES BY RAW FRESH GLAND (PANCREAS).

SIR,—Recent observations have suggested that insulin contains two fractions, one of which is concerned with the utilization of sugar by the tissues, and the other with glycogen deposition. This, it seems to me, very possibly provides the explanation of the divergent results of the treatment of diabetes with raw fresh pancreas, reported in your columns recently, and also experienced by previous experimenters since Cowles described his original success with the method in 1911 (*Boston Med. and Surg. Journ.*, 1911). Experiments upon which Mr. Howard and I have been engaged for over a year past have shown that the glycogetic fraction is less readily inactivated by the digestive ferments than the sugar-utilizing portion, so that when insulin is given by the mouth this fraction may, under suitable conditions, exert its effect on carbohydrate metabolism, although the sugar content of the blood does not fall as it does when insulin is given subcutaneously. If, therefore, fresh pancreas, or a preparation containing insulin, is administered orally in a case of diabetes where the hyperglycemia and glycosuria are entirely, or almost entirely, dependent upon defective storage, it may have a beneficial effect, but when there is defective sugar utilization such a method of treatment will be of little or no use. My clinical experience with various preparations of pancreas has tended to confirm these conclusions, and demonstrated that in suitably selected cases oral administration has a distinct place in the treatment of diabetes, but the type of case, the age of the patient, and the functional activity of the digestive apparatus, among other factors, influence the result, and indiscriminate reliance upon either fresh pancreas or preparations of the gland is, I believe, likely to lead to disappointment, and maybe to disaster, in many instances.—I am, etc.,

London, W.1, April 18th.

P. J. CAMIDGE.

### CHRONIC CYSTIC MASTITIS.\*

SIR,—Sir G. Lenthal Cheatle has discussed the most interesting problem among the many concerning diseases of the breast (*BRITISH MEDICAL JOURNAL*, January 3rd, 1925, p. 5). Striking features of the so-called chronic (cystic) mastitis, which Cheatle would call epithelial hyperplasia, are the numerous names which have been employed for it and the different opinions as to its relation to cancer. My studies of this breast lesion during a period of thirty years, and among almost 5,000 cases, lead me to conclude that chronic cystic mastitis (hyperplasia or abnormal involution) is a reaction of both the epithelial and connective tissue cells of the breast to some type of local or general irritant, the tendency of which is to a spontaneous return to normal. Cysts, single or multiple, are the most common end-results of the lesion, but even the cysts, which produce one or more palpable lumps, usually disappear. The disappearing tumour of the breast is a well recognized clinical fact. The older pathologists and surgeons never observed any of the types of chronic cystic mastitis except resultant simple or multiple cysts of long duration. Convincing evidence that chronic cystic mastitis usually disappears spontaneously is

\* Abridged.

afforded by the records and specimens in the surgical laboratory of the Johns Hopkins Hospital.

During my first ten years of association with Professor Halsted (down to 1900) the average duration of the lump in the breast was more than one year, and 80 per cent. of the tumours were cancer and 20 per cent. benign. Among these benign there were a few examples of cystic breast, single or multiple, and one or two of the non-cystic type of chronic mastitis. With each decade since 1900 the average duration of the lump in the breast has grown less, and the proportion of all types of chronic cystic mastitis increased rapidly. Since 1920 chronic cystic mastitis among patients who seek advice within one month after feeling the lump has become almost the most frequent lesion, and we are learning to recognize it clinically and not subject all the patients to operation.

The diagnostic problems in conditions of the breast have changed. When women wait until the lump has been present more than nine months, diagnosis is less difficult. Many of the benign lesions have disappeared, leaving cancer or the definite benign encapsulated adenoma or the rare benign cyst. During my first ten years' experience, on only a few occasions have we a record of a woman in whom a definite lump could not be palpated. Since our educational campaign in America women no longer delay. In my own clinic, since 1920, more than 50 per cent. of the women examined because of some breast complaint were not operated upon. We have found "lumpy breasts" of different types—those in which the multiple lumps are indefinite, and others with multiple definite lumps. When these cases have been submitted to operation in the past, as a rule some form of chronic cystic mastitis has been revealed.

The first important fact for the general practitioner is that there is a lesion of the breast which may produce pain, single or multiple lumps, with or without pain or tenderness, and discharge from the nipple, symptoms which as a rule did not influence the uninformed woman to seek the advice of a doctor; and in the majority of these cases all the symptoms disappeared. Now that women are becoming well informed, the majority (of the informed) seek medical advice for pain, discharge from the nipple, tenderness, and for indefinite single or multiple lumps, as well as for a definite single lump.

In my own clinic the number of breast cases in which it has been concluded that operation was not indicated has gradually increased. In 1921 the percentage of this group was 50, in 1924 almost 60. These women, because of the educational campaign, have come for examination at once. The "lumpy" breast, the "shotty" breast, and the dilated ducts beneath the nipple, form the larger proportion of this group, and as I have examples of all these types of breast in the laboratory, I know that the multiple indefinite lumps are due to chronic cystic mastitis or Cheatle's epithelial hyperplasia.

The recent report of Dr. Janet E. Lane-Clayton of a study of the results of 20,000 operations for cancer of the breast shows that the permanent cure depends upon two factors—the duration of the lump and the completeness of the operation. For early lumps, without gland involvement, the percentage of five-year cures varies from 70 to 80; in later cases with glands involved it falls to 15 to 20, and lower.

To-day the surgery of cancer of the breast is established, and most surgeons perform a faultless complete resection, but in most communities women still delay for the lump to disappear. Only among informed women do we see chronic mastitis as a very common lesion, and cancer in a very early curable stage. It is important for all members of the medical profession to become familiar with these clinical conditions of the breast which are brought to notice in very large numbers by any continuous educational effort. When palpation finds a definite single lump the problem at once becomes surgical and pathological. If the patient is over 20 years of age she should be sent to a hospital at once and the involved breast prepared as for the complete operation.

The majority of surgeons—surgical pathologist and pathologist—find little difficulty in recognizing, from gross and

frozen section, the encapsulated adenoma, the simple (blue-domed) cyst, and carcinoma, but when the area is not encapsulated, and not typical of cancer, confusion creeps in. In this group of non-encapsulated area without the definite gross and microscopic picture of cancer, some form of chronic cystic mastitis predominates.

I have now submitted over a hundred such cases to many surgical pathologists and pathologists in America, and always find a difference of opinion as to malignancy or suspicion of malignancy. The precancerous lesion of the breast is yet to be discovered or recognized.

There must be a practical working rule. First, when palpation of the breast finds a definite tumour, mass, or lump, or if there is any doubt as to such a finding, operation is indicated. Secondly, when the tumour is explored, all doubtful areas should be treated as cancer and the complete operation performed.

When the examiner learns to recognize the types of chronic cystic mastitis which produce lumpy and shotty breasts and the dilated ducts beneath the nipple, unnecessary operations will grow fewer. When the surgeon and pathologist learn to detect non-encapsulated areas of chronic cystic mastitis from cancer, the number of complete operations for benign conditions of the breast will also be reduced.

My conclusions are: (1) If cancer of the breast is to be cured by operation in 70 or more per cent., all women must be influenced to come for examination the moment a lump is felt. (2) When women do seek advice early, in at least 50 per cent. of cases careful examination will exclude any indication for operation. (3) When the definite early lump is explored, the chances are that in 50 per cent. it is not malignant and it will be necessary only to remove a zone of breast. (4) Removal of the breast, with few exceptions, is an illogical operation; it is too much for a benign and not sufficient for the malignant. (5) If the pathologist requires all the breast for microscopic examination there can be no conservative surgery of the breast. (6) A woman who presents the clinical picture of chronic cystic mastitis, or in whose breast at the exploratory operation gross and microscopic evidence of this lesion are found, runs no more risk of cancer than any other woman. Removal of the breast is not indicated for chronic cystic mastitis alone. (7) As suggested in your editorial (January 3rd, p. 32), an exploratory operation is always indicated, not only for a definite single lump, but for a doubtful one. At this exploratory operation the patient must be prepared for the complete operation, but the area should be cut into or excised, its gross appearance and the results of palpation considered, immediate frozen section made, and decision as to the extent of the operation made then and there. When there is doubt it is safer to perform the complete operation for cancer.

These conclusions are based on a continuous study for more than twenty-five years. Conservative methods have been forced upon us. In my own clinic 50 to 60 per cent. of the women who come for examination are not operated on, and in more than 50 per cent. of the early cases explored cancer is not found, and the breast is saved with no risk to the patient.—I am, etc.,

Baltimore, U.S.A.

JOSEPH C. BLOODGOOD.

### INTERNAL DERANGEMENTS OF THE KNEE.

SIR,—With regard to Mr. Wilson Stuart's article (JOURNAL, February 7th, p. 264), I would like to comment on each of the cases described.

Case 1 is obviously a case of repeated derangement of the knee-joint which will have to be operated upon eventually. The so-called "reduction" of the ruptured semilunar cartilage seldom leads to its "healing." The success of the manipulation seems to depend upon the torn portion of the cartilage being displaced towards the interior of the joint—probably in the neighbourhood of the crucial ligaments.

The history of Case 11 is one of repeated derangements, with locking at the time of consultation. In such a case I am accustomed to get the patient's consent to immediate exploration of the joint, should my manipulation be unsuccessful. This saves the patient much anxiety and a second anaesthetic, and the joint increased trauma.

In short, explore forthwith any knee-joint in which a second derangement has taken place.—I am, etc.,

B. WHITCUREN HOWELL, F.R.C.S.

London, W.1, Feb. 9th.

### SEVERE DERMATITIS FOLLOWING ULTRA-VIOLET LIGHT.

SIR,—In your issue of April 11th (p. 693) Drs. MacCormac and Moreland McCrea describe a case of severe dermatitis following ultra-violet irradiation. There is, I think, a very definite physical reason for what has happened, to which I venture to call attention. The kind of apparatus used is not mentioned, but the facts stated point to the mercury vapour quartz lamp.

Ultra-violet radiation differs from ordinary visible light only in wave-length. Whereas visible light ranges from a wave-length of 7,000 Angström units (1 A.U. =  $10^{-8}$  cm.) at the red end of the spectrum to 4,000 A.U. at the violet end; the ultra-violet comprises wave-lengths from 4,000 A.U. down to about 2,000 A.U. Sunlight has a spectrum ending at 3,000, and of this the range from 4,000 to 3,000 is ultra-violet. Professor Russ and others have shown that at the point 3,000 A.U. a marked change occurs in the effect of ultra-violet on living tissues and beings. Radiation of wave-length longer than 3,000 can penetrate to some slight depth. Radiation shorter than 3,000 is, however, very heavily absorbed even by the smallest thickness of skin, and is bactericidal.

Sunlight contains little radiation of wave-length shorter than 3,000, and the human skin and body have, by the process of natural selection, become suited to this form of radiation. The mercury vapour quartz lamp has a spectrum in which there is considerable intensity in the region from 3,000 to 2,000 A.U., and its use therefore exposes the body to a radiation to which it is not accustomed under natural conditions.

Of all artificial sources that most similar to sunlight in its spectrum composition is the carbon arc lamp.

There can be little doubt that, where general irradiation is desired for that stimulation of the body the mechanism of which is still but slightly understood, the carbon arc lamp should be employed. The tungsten arc and the mercury vapour quartz lamp should be reserved for those cases which can be described as "surgical," in which definite destruction of localized areas is desired; and these two lamps must be used with great care—as the case quoted by Drs. MacCormac and Moreland McCrea shows.—I am, etc.,

London, W.1, April 15th.

### INDIVIDUAL MEDICAL DEFENCE.

SIR,—Paragraphs 50-58 of the Annual Report of the Council of the British Medical Association to the Representative Meeting next July, on the subject of individual medical defence, require the most careful attention of all members. By "individual medical defence" the Council means the work now done by the Medical Defence Union and the London and Counties Medical Protection Society (and by a sister society in Scotland). When these societies came into existence many years ago, there was, I gather, no desire on the part of the British Medical Association to undertake "individual medical defence": a short-sighted attitude, to my mind, but ancient history now. For several years resolutions in favour of the Association changing its policy in this matter have been debated at the Representative Meetings, but have always been defeated; the last occasion was in 1924.

Now for the first time the Council is giving support to the principle, chiefly on the ground that individual defence is that aspect of professional organization which most appeals to the newly registered, and that the British Medical Association is handicapped in its efforts to enrol the entire profession by its inability to offer the kind of help which new entrants most require, or believe they require; there have been other arguments, of lesser validity, some of which you allowed me space to comment upon last year (BRITISH MEDICAL JOURNAL, June 14th, 1924, p. 1072). But the Council finds an insuperable obstacle in the Memorandum of Association, which (as it

tells us) will not allow the British Medical Association to take up individual defence. To circumvent this difficulty, as the Memorandum probably cannot be altered in this respect, it is suggested that a "separate organization" should be "initiated" to give such members as desire it and are willing to pay a separate subscription for it, full medical defence as given by the existing societies. The Council asks for authority to prepare a draft scheme and to circularize the profession to find out whether 6,500 will join in it. It states that the organization would have to be a separate company, on the governing body of which the Association could arraign for unofficial majority representation. It does not, however, state who is to pay the expenses of preparing and circulating the draft scheme and of floating the company: presumably the company, if, as may quite possibly be the case, it is *ultra vires* for the Association to do so.

That is, in outline, what members of the British Medical Association have to consider.

Although the British Medical Association cannot back the scheme financially, or associate itself officially with the company, the Council apparently hopes to control it unofficially. But once the company has been started, the subscribing members of it will have complete control, because at their annual meetings they will be able to elect their own officers and to modify the constitution of the company. The Council of the British Medical Association may benevolently draft the first Memorandum of Association and provide the first set of office-bearers, but cannot possibly, even unofficially, impose the faintest shadow of authority over the new company when once it is floated. The company, if a majority of the members wish, can go entirely counter to the policy of the Association; not a very likely supposition, doubtless, but not an impossible one. The British Medical Association, in other words, will not be able to approach new members of the profession saying, "Join us, and you can join an individual defence society which is part of us and under our control"; such a statement would be untrue. It follows that the argument as to strengthening the position of the British Medical Association in respect of the newly registered falls to the ground: the Association will be in no stronger position than before.

Further, no part of the Association's funds can be at the back of the new company, which must start without any reserve fund. The British Medical Association must disclose this fact in approaching the newly registered; nay, must even emphasize it, because few of the recently qualified are likely to think of investigating that matter for themselves. The Association must say, "Join us, and we will collect, if you wish, your subscription to an individual defence company which has been started under our auspices, but over which we exercise no control whatever and are in no way responsible for; and please note that this company has no reserve fund, whereas the older and larger societies have funds running into many thousands of pounds." A large reserve fund is not absolutely indispensable to the work of a defence society; both the existing societies started without any, as everyone knows. But reserves are so advantageous that the society which has them is by that fact alone able to offer better defence, better value for his subscription to the individual than the society which has not. Nor is this a fanciful objection, or a purely theoretical one. In a single *cause célèbre* of 1924, the London and Counties Medical Protection Society is rumoured to be seriously out of pocket, although victorious.

As to the management next. By years of trial and elimination the existing societies have obtained councils of managers highly experienced in the work of individual defence. It would be foolish to say that the councils of the Defence Union and the Protection Society are invariably right; but there is extraordinarily little dissatisfaction among their twenty odd thousand members, by whom directly and indirectly the entire councils are elected.

Dr. Morton Mackenzie told the Council of the British Medical Association that the existing societies have been given every opportunity of entering into co-operation, and have refused. The explanation should be added that what Dr. Mackenzie alludes to is a suggestion made at a joint

conference that the defence societies should grant some special concessions to members of the British Medical Association—for example, waiving entrance fee, or reduced subscription. To call this "every opportunity of entering into co-operation" is not fair to Dr. Mackenzie's own organizing and administrative abilities.

The scheme can be summed up fairly simply. It is that a new "individual defence" society shall be formed, confined to members of the British Medical Association, if 6,500 are prepared to join as members. The new body is to do the same work as the existing societies, at the same rates of subscription. It is not to be part of the British Medical Association, nor is it bound to remain even unofficially under the control of the British Medical Association for more than its first year. It will not enable the British Medical Association to offer to the newly registered any advantages whatsoever that are not at present offered. It will start handicapped by lack of reserve funds, by lack of experienced management, by a membership smaller (that is, by overhead charges greater per member) than those of the existing societies. It means that three offices, three paid secretaries, three office staffs, three firms of solicitors, three auditors, three advertisement accounts are to be paid for out of the pockets of the medical profession to do necessary work now done, and well done, by two. Forty-five years ago the scheme would have been a benefit to the profession. To-day it seems to me wasteful and unnecessary. I am ready to vote for it and to join it if I am convinced that it is for the benefit of the profession; but at present I am not so convinced.—I am, etc.,

London, S.W., April 20th.

HENRY ROBINSON, M.D.

## CONFERENCE OF MENTAL HOSPITAL AUTHORITIES.

### THE ASYLUM NURSING SERVICE.

A NATIONAL conference of mental hospital authorities (medical superintendents and representatives of visiting committees) was held on April 21st and 22nd, under the chairmanship of Sir FREDERICK WILLIS, chairman of the Board of Control. On the first day the nursing service in mental hospitals was discussed, and on the second day the provision of further mental hospital accommodation.

Mr. Neville Chamberlain, the Minister of Health, in opening the conference, expressed the hope that some practical result would emerge from the report of the departmental committee on mental nursing. The nursing service for the insane, he said, should be at least equal in efficiency and status to any other branch of nursing. A very great distance had been traversed from the old-time "keeper" to the modern asylum nurse, and the courses of training and examinations organized by the Medico-Psychological Association during the last thirty years had been a great factor in progress; more than 17,000 nursing certificates had been granted by the association. With regard to the second subject before the conference, the question of further accommodation was becoming increasingly urgent, not because the number of insane was growing at a greater rate than the population, but because the incidence was decreasing so slightly that with the growth of population the number of persons in need of such accommodation also increased. When he formerly held his present office he was responsible for the Mental Treatment Bill, which passed the House of Lords, but went no further owing to the general election of 1923. It was not possible to reintroduce the bill while the Royal Commission was sitting, but he thought there was general agreement as to the need for legislation to enable early treatment to be obtained without certification by persons in the incipient stages of the disorder, and he hoped it would be his good fortune before he relinquished office to add a measure of this kind to the Statute Book.

Sir Frederick Willis said that as the outcome of the conference of mental hospital authorities in 1922 three departmental committees were set up. One of these dealt with dietaries, and many of its recommendations had already been adopted. A second dealt with records, and this had framed new rules, which had been approved by the Lord Chancellor; the speaker regretted that it was not possible still further to simplify the keeping of records. The remaining committee, which was presided over by Dr. C. Hubert Bond, had to do with nursing, and its report was available for discussion that day. He announced his intention not to accept any resolutions.

P. King, W. M. F. Det,

## Obituary.

SIR RICKMAN JOHN GODLEE, Bt., K.C.V.O., M.S.,

Consulting Surgeon to University College Hospital;  
Formerly President of the Royal College of  
Surgeons of England.

We regret to have to record the death, on April 20th, after a few hours' illness, of Sir Rickman Godlee, at his house at Whitechurch, near Pangbourne, where he had gone to live after retiring from practice in 1920.

Rickman John Godlee was the son of Rickman Godlee, barrister, who married Mary, the daughter of Joseph Jackson Lister; Godlee was therefore the nephew of Lord Lister, who exercised a great influence on his character and career. The Godlees, like the Listers, were Quakers, and this was a second great influence on Godlee's character.

A third influence arose out of his skill as a dissector and his remarkable ability as a draughtsman, which caused his services as an illustrator to be eagerly sought while he was still quite a young man. This is, however, to put the fact rather low, for Godlee himself was an artist of some ability and a fine judge of etchings and mezzotints.

Rickman Godlee was born on February 15th, 1849, at Upton, Essex, where also Lister's father lived and there was a considerable colony of Quakers, the Listers being among the chief members of it. He was educated first at a school in Tottenham, and then at University College, London. He took the degree of B.A. Lond. in 1867, and then entered University College Hospital Medical School. His chief friends there were Marcus Beck, Vivian Poore, and John Tweedy. These three were early appointed to the staff of the hospital. Godlee, who, after holding the usual resident appointments, had become surgical registrar, was passed over, to the surprise of his contemporaries and to the chagrin of the students. He became assistant surgeon to Charing Cross Hospital. Within a few years, however, an opportunity occurred of repairing the mistake, and Godlee became assistant surgeon to University College Hospital, in due course surgeon, and eventually consulting surgeon. He was also professor of clinical surgery in University College, and when he retired was made emeritus professor.

The position of the medical school of University College Hospital was at the time of Godlee's appointment to the staff rather unusual; the number of students was large and the standard among them high. The staff, at least the younger members of it, were not exactly popular with staffs of other schools; they were accused of looking out for novelties and talking too much about physiology, pathology, and bacteriology, thereby disturbing the comfortable old ways. Marcus Beck, assistant surgeon, was the leading spirit. He was a cousin of Lord Lister, had lived with him while studying at Glasgow, and was one of his most faithful disciples. Beck was the first surgeon in London to carry out the antiseptic system of surgery with understanding; he had a powerful ally in the late Mr. (after-

wards Sir Henry) Howse of Guy's Hospital, and a welcome recruit in Godlee. Their efforts, persistent and enthusiastic as they were, only slowly produced an effect upon the ordinary practice of the London hospitals; gradually they were winning over the younger men when Lister was appointed professor of clinical surgery at King's College in 1877. Thereafter, with the master on the spot, progress was a little less slow, but even then not rapid. The eventual triumph is a commonplace of surgical history and may be read more at length in Godlee's *Life of Lister*. As Godlee said in the preface to his first edition, "During my studentship I was able to compare the old system of surgery, then in full swing at University College Hospital, with Lister's practice in Edinburgh. Few are left who had so good an opportunity of making this comparison, or of watching the whole course of the modern revolution in surgery, or of noting the heresies and schisms as they crept in."

Godlee graduated M.B., B.S. Lond. in 1872, and M.S. in 1873. His long connexion with the Royal College of Surgeons of England began in 1872, when he took the diploma of M.R.C.S. He became F.R.C.S. in 1876 and was elected a member of council in 1897, at the same time as Sir Watson Cheyne and the late Mr. Edmund Owen. In 1911 he succeeded Sir Henry Butlin (who died in office) as president, and served for the two following years (1912, 1913). In his last year as president he delivered the Hunterian Oration entitled "Hunter and Lister"; it was mainly concerned with the history of the museum of the Royal College of Surgeons of England and with the orator's aspirations for its future. As Godlee said in that lecture, he had had the privilege of passing the best years of his life in the closest intimacy with Lister; and both on that account and because of his command of a good English style he was marked out to be the biographer of his uncle. The book was very well done and was an immediate success. It not only gave an authoritative and well documented

Photograph by]

J. Russell and Sons, London.

SIR RICKMAN JOHN GODLEE, Bt.

account of Lister's work as a surgeon and man of science, but it contained also a picture of the simple, homely, but full life of the Society of Friends, a picture which will remain a permanent contribution to the social history of English society. The first edition appeared at the end of 1917, and a second edition was called for within a few months. A third edition appeared, with some additions, at the end of last year; it was reviewed in our issue of December 27th (p. 1205).

Sir Rickman Godlee rendered many services to the Royal College of Surgeons of England besides those done when he was its president. On completing his *Lord Lister* he, as acting executor, presented to the College all his uncle's scientific and surgical possessions. In this way the College became the owner of Lister's surgical instruments and appliances, the apparatus used in his more important experiments, as well as all his original manuscripts and records of his investigations. It was a fortunate circumstance that the description and cataloguing of this collection—the outfit of the greatest surgeon of modern times—should have been entrusted to that rare and ripe

scholar, Mr. Alban Doran. In writing the description of the Lister collection Mr. Doran had the advantage of Sir Rickman's counsel and knowledge. Many were the conferences they had, all of which usually ended by the participants comparing how time was dealing with their respective healths, for they were born within a day or two of each other. Mr. Doran never wearied in pointing out that the three young medical men of his time who had given their attention to pathology in their younger days had all become baronets. These young men were Sir James Goodhart, Sir Henry Butlin, and Sir Rickman J. Godlee. As a matter of fact, in his younger days Godlee was both anatomist and pathologist, but of the two he would have preferred to be regarded as anatomist. Anatomy at that time was a recognized path to a surgical career. On taking his Fellowship in 1876 he began the preparation of an *Atlas of Human Anatomy*. On the title-page he informs the reader that it "illustrates most of the ordinary dissections and many not usually practised by the student." The *Atlas* was accompanied by an explanatory text. Over 100 dissections were made for its preparation, mostly by himself, during the years from 1876 to 1880—the years during which he waited for patients. Each dissection was drawn by himself in pencil, vessels and nerves being given distinctive colours. His drawings were reproduced on stone. The *Atlas* was brought out by Messrs. Churchill in 1880, and never received the recognition at the hands of the profession which its merits should have secured for it. On giving the College the Lister collection Godlee added his own drawings and records to the gift. He included the drawings prepared for his *Atlas*, and they show him to have had high gifts as draughtsman and artist. The lithographer, while he retained the clarity of the originals, has lost much of the softness of Godlee's artistry. In this collection of drawings are included delicate and beautiful wood engravings of the microscopical structure of tumours and of other pathological conditions. These Godlee drew on wood from his own preparations. They were cut by the greatest wood engraver of the time—the elder Butterworth. The wood engravings were published in Quain's *Anatomy* and in *Erichsen's Surgery*.

There can be no doubt whence Godlee drew his gifts as an artist—from his mother's family. In the Lister collection are drawings done by the great surgeon in 1862-64 when he was planning his operation for resection of the carpus and wrist-joint. Some are in black and white, some in water-colour, some in oils, but all show that Lister would have made a name as an artist and draughtsman. Godlee's style resembles that of his uncle; perhaps he had the more delicate and accurate pencil. Godlee was not only an artist, but he loved the highest forms of art. He was the possessor of a valuable collection of etchings, many of which were fine examples of Rembrandt's best.

Amongst the drawings which Sir Rickman Godlee presented to the College are some of historical importance. On May 20th, 1874, he opened an abscess connected with an acute necrosis of the tibia and immediately mounted some of the pus and examined it under the microscope. He made accurate drawings, by aid of a camera lucida, of certain curious minute bodies detected by him in the pus. They were arranged in rows or chains. This drawing he presented to the College with others. On it he has written, "This was, so far as I know, the first time that organisms were seen in the pus of an abscess immediately it was opened." Another drawing, made February 1st, 1875, represents the same organism arranged in chains. The drawings are done in Godlee's most finished style. Having made his drawings, he did nothing more; he did not name or describe the characters of the organism he had observed. They were streptococci. The classical paper by Sir Alexander Ogston, in which streptococci and staphylococci were described and named for the first time, appeared in 1881. Nevertheless, Godlee had seen and drawn streptococci in the pus of a newly opened abscess in 1874, when he was 25 years of age.

When in the early stage of the great war Belgium was overrun by the German armies many members of the medical and pharmaceutical professions were reduced to great straits, and some of them sought refuge in this country; an appeal was made to the doctors and

pharmacists in this country to come to their aid. At the first meeting of a committee formed for the purpose Sir Rickman Godlee was in the chair, and he retained that position during the war and until, happily, the need for the continuance of the fund ceased. He gave a great deal of time to the work of organizing the collecting and distribution of the money. His services were recognized by the grant of the Médaille du Roi Albert in September, 1919.

Godlee was long a member of the British Medical Association. He was secretary of the Section of Surgery at the Annual Meeting in Dublin in 1877, and vice-president at that in Newcastle in 1893. He did not take any very active part in the public affairs of the profession, except when president of the Royal College of Surgeons; nor did he write much, but what he wrote was of a very high order of merit. His best known book was prepared in association with Sir James Fowler, and was entitled *Diseases of the Lungs* (1898). It was largely the result of experience gained at the Hospital for Consumption, Brompton. It was a very solid contribution to the subject and had a very great effect on the surgery of the thorax at the time. Early in 1890 he contributed to our columns a course of three lectures delivered at the Brompton Hospital on the surgical aspects of hepatic abscess. They commenced with the sentence, very characteristic in its dry humour, "It is needless to tell anyone connected with this institution that the chest contains many more organs than the student of anatomy is disposed to put into it." The conclusions with which he ended his third lecture still, we believe, stand as a sound expression of the main principles of hepatic surgery.

Godlee's growing cataract may have impaired his eyesight in his later years; it certainly did not dim the vision of his intellect. He kept throughout his life the freshness of vision so often confined to youth. When he retired to his farm he opened up new interests—botanical, zoological, and geological. And he never tired in well-doing.

Godlee received many honours; he was surgeon to the household of Queen Victoria, and surgeon-in-ordinary to King Edward VII and King George V. He was created a baronet in 1912 and received the K.C.V.O. in 1914. He married in 1891 the daughter of Frederick Seebohm, LL.D., D.Litt., of Hitchin. He is survived by Lady Godlee, with whom much sympathy will be felt in her bereavement. They had no children.

The Very Rev. LANCELOT PARKER BOOTH, M.D., D.D., died at Seapoint, Cape Town, on March 28th, aged 74. He was the son of Mr. L. P. Booth of Bishop Auckland, and took the LL.B. and S.E.D. in 1876, after which he entered the service of the colony of Natal, in the Indian Immigration Department. Determining to enter the Church, he was ordained in 1883 by the Bishop of Maritzburg as assistant to the bishop for Indian missions, subsequently becoming diocesan superintendent of Indian missions and Canon of Maritzburg. In 1887 he obtained the degrees of M.D. and C.M. from Toronto University, which later on, in 1902, conferred upon him its degree of D.D. also, and in 1896 he graduated as M.D. of Durham. In 1900 he was appointed dean of St. John's, Kaffraria, and rector of Umata, and at the same time resumed the medical profession, to serve in the South African war as medical officer of the Natal Indian ambulance, and received the Queen's medal with two clasps. In 1912 he removed to Cape Town, where he was for a short time vicar and subdean of St. George's Cathedral, and in 1913 was appointed rector of St. Barnabas, Cape Town. During the recent great war he served in France as a temporary captain in the R.A.M.C., his commission as such being dated November 14th, 1916, doing duty with the South African native labour corps. His only son, Lieutenant Ainslie Booth, R.A.M.C.(T.C.), was killed in action in France on April 30th, 1916.

Dr. VICTOR JACQUES, a well known Belgian anthropologist and honorary professor in the Brussels Faculty of Medicine, has died at the age of 71.

The death is announced of Dr. MORIX, president of the Swiss Antituberculosis Association.

## The Services.

### THE NAVAL MEDICAL COMPASSIONATE FUND.

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on April 17th, when Surgeon Vice-Admiral Joseph Chambers, C.B., C.M.G., Medical Director-General of the Navy, was in the chair, the sum of £125 was distributed among the several applicants.

### INDIAN MEDICAL SERVICE.

The annual dinner of the Indian Medical Service in London will be held at the Trocadero Restaurant on Wednesday, June 17th, at 7.15 p.m.

## Medical News.

THE Malaria Commission of the League of Nations Health Organization, which consists of representatives of Great Britain (Colonel S. P. James, of the Ministry of Health), France, Germany, Italy, Poland, Rumania, and Holland, has arranged a scheme of inquiry into the malarial conditions, first in Egypt, Palestine, and Syria, and then in Turkey, Asia Minor, Sicily, Corsica, and Spain. It is to begin in May and to be continued until the end of September. The Commission has in hand a report on malaria in Albania, and is considering the appointment of additional corresponding members from British India, the United States, and France. It is also considering from the economic point of view the use of cinchona alkaloids as well as of quinine.

DURING the annual meeting of the Canadian Medical Association at Regina, from June 22nd to 26th, an address will be given by Mr. H. W. Carson, F.R.C.S., president of the Hunterian Society of London. Mr. Carson has been specially invited, through the British Medical Association, as the guest of the Canadian Medical Association.

DR. DOUGLAS E. FINLAY, the Representative of the Gloucestershire Branch in the Representative Body of the British Medical Association, has been elected a member of the Gloucester City Council without a contest.

DR. E. F. BINDLOSS of Farnborough secured first place on the poll in the recent election of district councillors, and his wife headed the poll in the election to the local board of guardians.

THE next social evening at the Royal Society of Medicine will be held on Monday, May 4th, at 8.30, when Fellows and guests will be received by the President, Sir St. Clair Thomson. At 9.30 Dr. Robert Hutchison will give a short address on "Dr. Samuel Johnson and Medicine" (illustrated with eighteenth century portraits).

DR. ANDREW BALFOUR, director of the London School of Hygiene and Tropical Medicine, will read a paper on the trend of modern hygiene before the Royal Society of Arts (John Street, Adelphi, W.C.2) on Wednesday, April 29th, at 8 p.m. The chair will be taken by Sir George Newman, Chief Medical Officer, Ministry of Health.

THE annual meeting of the Ontario Health Officers' Association will be held on May 4th, 5th, and 6th in the Mining Building of the University of Toronto, under the presidency of Dr. C. N. Laurie of Port Arthur. The proceedings will open with an address by Dr. J. W. S. McCullough, chief medical officer of health for the province.

THE Fellowship of Medicine announces that on May 11th a three weeks' course in diseases of the nose, throat, and ear, including an operative surgery class, commences at the Central London Throat, Nose, and Ear Hospital. At the Maudsley Hospital a month's course in psychological medicine will be held from May 4th to 28th. A two weeks' course in diseases of infants at the Infants Hospital from May 18th to 30th includes clinical demonstrations, "round table" consultations, lectures, and four visits to centres away from the hospital. An afternoon course in dermatology will take place at the Hospital for Diseases of the Skin (Baker's Hospital) from May 18th to 30th. For those in general practice it is proposed to hold a two weeks' course at the London Temperance Hospital from May 18th to 29th, Saturday excepted. At 4.30 p.m. each day a clinical demonstration (with cases) will be given, followed by a short lecture at 5.30. Further details of these courses may be obtained from the secretary of the Fellowship, No. 1, Wimpole Street, W.1.

A course of lectures on pathological research in its relation to medicine will be given in the lecture room of the bacteriological department of the Institute of Pathology and Research, St. Mary's Hospital, Paddington, W.2, on Thursdays at 5 p.m., commencing on April 30th, when Sir Almoth E. Wright, M.D., F.R.S., Principal of the Institute, will speak on chemotherapeutic agents. On May 7th Professor W. E. Dixon,

M.D., F.R.S. (Cambridge), will discuss the cerebro-spinal fluid, with special reference to pituitary secretion. The last lecture, on June 18th, will be given by Mr. R. Robison, D.Sc., on the chemistry of the calcification of bone. The lectures are open free to members of the profession and to students in medical schools.

A SERIES of six clinical demonstrations on types of mental disease will be given at the Maudsley Hospital, Denmark Hill, S.E.5, by the medical superintendent, Dr. E. Mapother, on Wednesdays at 2.30 p.m., commencing on May 6th, when he will deal with congenital and early types. On May 13th psychoses associated with epilepsy and with syphilis will be discussed. The last demonstration is fixed for June 10th, when states of exaltation and depression will be dealt with. The fee for the six demonstrations, which will be illustrated by numerous cases, will be one guinea.

At the annual medical mission meeting of the Society for the Propagation of the Gospel in Foreign Parts, on April 22nd, under the chairmanship of the Bishop of Exeter, Rev. P. S. Drewe, M.R.C.S., L.R.C.P., Pondoland, Cape Province, gave an lantern slides, and Dr. H. H. Weir, secretary of the medical missions department, also spoke. The report of the medical missions department shows that the general medical fund for 1924 amounted to £14,538, an increase over any previous year. Very few male practitioners, it is said, are volunteering for service as medical missionaries.

DR. J. WRIGHT MASON, who, as recorded in our issue of April 18th (p. 763), was recently presented with a silver salver by the head officials of the Corporation of Hull, has been entertained to a complimentary dinner by members of the medical profession in Hull. Dr. Mason has lately retired from the post of medical officer of health for Hull after forty-four years' service.

THE conference held at Hoddesdon in September, 1924, on special libraries and information bureaux has resulted in financial support being obtained from the Carnegie United Kingdom Trustees for a period of two years in order to give the new movement an opportunity of becoming self-supporting. Mr. G. W. Keeling has been appointed organizing secretary to the committee. A second week-end conference will be held at the end of September and a directory of special libraries and information bureaux for the United Kingdom is in contemplation.

THE thirty-eighth congress of the French Society of Ophthalmology will be held at Brussels on May 11th, when the following papers will be read: "Belgium, the classical land of ophthalmology," by Professor De Lapersonne; "The etiology of trachoma," by Dr. Morax; and "Was the artificial eye known to the ancients?" by Professor M. van Duyse of Ghent. An exhibition of optical instruments and pharmaceutical products will be held at the same time as the congress.

THE well known Belgian surgeon, Professor A. Depage, has been nominated Grand Officer of the Legion of Honour.

MESSRS. CONSTABLE AND CO., LTD., have published the agreement, protocol, and final act of the first opium conference (9d. net) and the convention, protocol, and final act of the second opium conference (2s. 6d. net). The first document was signed at Geneva on February 11th and the second on February 19th. The effect of the decisions of the conferences was discussed in a leading article on the international control of drugs of addiction published in the BRITISH MEDICAL JOURNAL of March 28th (p. 618).

THE nineteenth Voyage d'études médicales to the health resorts of France (organized solely for the purpose) will take place during the first part of the scientific direction of Professors Carnot and Rannery, and will be devoted to the resorts of the North and East. The party will assemble at Berek-sur-Mer and will first visit Paris-Plage, Lille, and Saint-Amand, and will then go to Belgium to visit Brussels, Spa, Luxembourg, and Mondorf. Returning to France via Niederbronn and Morsbronn, the party will visit Strasbourg, Schirmeek, le Hohwald, Sainte-Odile, Chateaufort, and Ribeauvillé, Colmar, Sultzmatz, Sultzbach, Munster, les Trois Epis, le Linge, le Col de la Schlucht, and Gérardmer. Crossing the Vosges again it will then follow the road of the Cretes and visit Bussang, Luxeuil, Plombières, Bains-les-Bains, Bourbonne, Martigny, Contrexéville, and Vitte. First-class accommodation is arranged throughout the journey and at the hotels. For further particulars apply to Madame Juppé-Blaise, delegate of the French Spas, Office Français du Tourisme, 56, Haymarket, S.W.1.

THE Société française d'orthopédie dento-faciale will hold a congress at Brussels from May 21st to 23rd, when the following papers, among others, will be read: "Historical review of the different methods of transverse maxillary expansion," by M. Izard; "Physiotherapy of maxillo-dental malformations," by M. Watry; and "Terminology of orthodontia," by M. Izard.

## Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Authors desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Financial Secretary and Business Manager, 423, Strand, W.C.2, on receipt of proof.

ALL communications with reference to advertisements as well as orders for copies of the JOURNAL should be addressed to the Financial Secretary and Business Manager, 423, Strand, London, W.C.2. Attention to this request will avoid delay. Communications with reference to editorial business should be addressed to the Editor, BRITISH MEDICAL JOURNAL, 423, Strand, W.C.2.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—not necessarily for publication.

Communications intended for the current issue should be posted so as to arrive by the first post on Monday or at latest be received not later than Tuesday morning.

THE telephone number of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is Gerrard 2630 (Internal Exchange). The telegraphic addresses are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westrand, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westrand, London.

MEDICAL SECRETARY, Medusera Westrand, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: Baedins, Dublin; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: Associate, Edinburgh; telephone: 4361 Central).

### QUERIES AND ANSWERS.

#### INCOME TAX.

Succession: Partnership Introduction.

A. C. D. took over a practice as from January 1st, 1924, after a "partnership introduction" of three months from October 1st, 1923, on a basis of half-share of profits and expenses. Book debts were not taken over.

For the financial year ended April 5th, 1924, the average profits for assessment are presumably those of the three years to December 31st, 1923, and no difficulty will arise in respect of the book debts, as those profits can conveniently be made to include all debts received up to that date. If the assessment—that is, average profits less average expenses of both partners while working the practice as proprietors of the whole or part—be £x, "A. C. D.'s" share will be  $(\frac{1}{2} \text{ of } \frac{1}{4} \text{ plus } \frac{1}{4} =) \frac{3}{8}$ , and he will be liable to account for tax on that proportion, less any personal allowances to which he may be entitled. For the financial year ended April 5th, 1925, he will be liable on the average gross earnings over the three previous years, less the expenses incurred in working the practice in those years. His predecessor can no doubt supply the appropriate figures for 1922 and 1923, and for 1924 he should take the value of his bookings for his gross receipts and compute the amount of his expenses on the usual lines, excluding the expenses of acquiring the practice. If he can subsequently—that is, by April 5th, 1926—show that the assessment so calculated exceeds his earnings for 1925 (on the basis of the value of his bookings less expenses for that year), and that the reduction is due to some specific cause since or by reason of his succession to the practice, he can claim an adjustment of his assessment by repayment of tax or by any other convenient method.

### LETTERS, NOTES, ETC.

#### A NEW MOSQUITO BREEDING PLACE.

UNDER this heading in our issue of March 7th (p. 488) we drew attention to an observation recorded by Dr. W. E. Haworth in the *Transactions of the Royal Society of Tropical Medicine and Hygiene* to the effect that mosquitoes breed in the crowns of coco-nut palms. In our issue of March 21st (p. 586) was published a note from Dr. J. C. Ryan to the effect that in a book, *Health Preservation in West Africa*, published by him in 1914, reference was made to this source of danger. We have since received a letter from Dr. Haworth enclosing the following quotation from Dr. Ryan's book:

"A universal custom amongst West African natives in felling trees, irrespective of the size, is to leave the stumps standing 2 ft. or 3 ft. high. These are frequently hollow in the centre; the stumps of palm trees are always so. During rain these cavities become filled with water, in which mosquitoes readily lay eggs. Soon they become alive with larvae; so numerous, indeed, that ants stationed on the edge of the holes can easily prey on them, and have been seen doing so by the writer."

Dr. Haworth observes that Dr. Ryan's reference is to breeding in the hollows formed in the stumps of palms which have been cut down; his (Dr. Haworth's) was, as has been said, to the breeding of mosquitoes in the crown of leaves of living palms.

Dr. Haworth tells us that he can find no reference in Dr. Ryan's book to this. Dr. Haworth offers to send Dr. Ryan a copy of his paper on mosquitoes and coco-nut palms.

#### EASY WRITING AND HARD READING.

In a note published last week (p. 753) the phrase "Easy writing's d—d hard reading" was attributed to Byron. Dr. C. O. HAWTHORNE writes to recall Sheridan's lines:

"You write with ease to show your breeding,  
But easy writing's curst hard reading."

(Clio's Protest: Moore's *Life of Sheridan*, vol. i, p. 155)

Sir STCLAIR THOMSON has sent a note on the same subject. He writes: In the JOURNAL of April 18th it is remarked, in an annotation on the revision of manuscripts, that Amaleto Franco "would have agreed with Byron's epigram had he known it—Easy writing's d—d hard reading." Is this quotation from Byron authentic? If so, I presume it means hard "proof reading," for Byron was no hard reader, nor does the writing of poetry necessarily entail reading, d—d or otherwise. I have always heard the bon mot in association with public speaking and Sheridan, who, when complimented on his facile speech, replied, with his pleasant Irish accent, "Easy speaking, me boy, means d—d hard thinking." If not *vero*, I think the story is much more *ben trovato* in this association than in connexion with poetry writing and hard reading.

It may be that, quoting from memory, we attributed to Byron an epigram that belonged to Sheridan, although we are under the impression that Byron used the phrase. However this may be, we suggest that Sir Stclair Thomson has not taken the point; which is that easy writing for the author makes hard reading for the reader.

#### TRANSFUSION IN CARBON MONOXIDE AND COAL GAS POISONING.

DR. JAMES HOLMES (Bury) writes: The recent tragic death of a medical friend (who had been exposed to motor car fumes), after unavailing efforts at resuscitation by several medical colleagues for nearly twelve hours, has caused much regret and worry to me, especially as we are at present almost, if not quite, helpless in these cases. I therefore venture to suggest a possible method of treatment which has not, as far as I know, been tried. Though the method may be somewhat heroic, it is founded on well known facts. As those who have studied these cases know, the gas combines with the red blood corpuscles and prevents them carrying oxygen to the tissues, and we know no method of separating it from them. The result is that attempts at artificial respiration, with or without tracheotomy, are bound to fail. In these circumstances I venture to suggest that transfusion, with, in suitable cases, tracheotomy, is a successful treatment. The corpuscles, free from the gas, able to carry oxygen, while penetration would, in plethoric cases, not only prevent the risks of high blood pressure, but also get rid of useless corpuscles.

#### LEMON CHEESE.

MR. G. D. ELSDON, B.Sc., F.I.C., has recently reported to the Society of Public Analysts the result of an investigation of "lemon cheese." He has come to the conclusion that it should consist substantially of butter, eggs, sugar, and lemons. An examination of commercial recipes and samples showed that the article manufactured on the large scale is frequently of inferior quality, and that preparations are on the market containing no eggs, no butter, and little fat of any description; and having from 50 to 50 per cent. of added water, the presence of which is masked by the addition of "British gum" and possibly gum tragacanth. He suggests that this and similar preparations should be amenable to control, and that it is undesirable that articles of variegated composition should be presented to the public under the same description.

#### ASTHMA.

DR. R. D. MILLER (Hull) writes: In view of recent discussion on the cure of asthma the following case may be of a certain amount of interest. I have lately been attending Mrs. W., aged 62, for asthma and bronchitis of a peculiarly stubborn kind, and of about twenty years' duration. Her nose and nasopharynx have been examined on more than one occasion. Two months ago she developed an exceedingly severe attack of measles with a temperature of 104°, her whole body becoming one continuous mass of bright scarlet. Apart from any other consideration, I was extremely anxious about her chest, expecting her to develop some form of pulmonary complication severer than is common after a juvenile attack of measles. To my surprise her chest began to clear up, and before the rash had faded her asthma had entirely left her, and her lungs sound healthy. That her rash was due to measles there is no doubt, it having been seen by my chief independently from me. She had also had measles in childhood. I have seen her on several occasions lately and she is able to go about during inclement weather with no inconvenience at all.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 39, 40, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 187.

## An Address

ON

## THE SPECIFIC ACTION OF DRUGS IN TUBERCULOSIS.\*

BY

W. E. DIXON, M.D., F.R.S.,

READER IN PHARMACOLOGY, UNIVERSITY OF CAMBRIDGE.

It is now well recognized that a patient suffering from tuberculosis who is placed under the charge of a doctor will, for a time at least, improve in health no matter what drugs, vaccines, or specialty of treatment may be employed. The beneficial result is due in this, as in other diseases, to efficient nursing, to the regulation of food, exercise, and sleep, and to light and fresh air. If only this effect were clearly recognized the number of "treatments" in vogue for this common disease might be diminished. The enthusiastic physician sometimes begins the new treatment so soon as the patient enters his wards, and he is apt to put down the wonderful effects which may follow to the new drug, a view which unfortunately he neglects to rectify when the patient dies. General hygienic measures are of primary importance in treatment, and it is not until all the beneficial effects, which we know will ensue from these alone, have been exhausted that we have any right to ascribe an effect, beneficent or otherwise, to a special treatment.

Drugs are employed in tuberculosis either with the object of attacking and preventing the growth of the tubercle bacillus or other organisms with which the disease may be associated, or of neutralizing poisonous toxins, or of removing or relieving symptoms. It is to the first group that I am directing your attention to-day.

The ideal for which we search is an internal antiseptic, something which will prevent the growth of the tubercle bacillus without injuring the host, and this principle of internal antiseptics has now come to be termed "chemotherapy."

## COAL-TAR DERIVATIVES.

The ordinary common antiseptics like phenol and the coal-tar derivatives (creosol, guaiacol)—mercury perchloride and formalin, for example—act in the same way on almost all micro-organisms; their antiseptic action is greatly diminished by admixture with serum, and when injected into the animal body they destroy the animal before they destroy the parasites. Innumerable attempts have been made to synthesize more active antiseptics, and two recent products of the laboratory I will mention. By brominating cresol a tetrabromocresol is obtained, which is 250 times more active than phenol and only half as toxic; by brominating naphthol tribromonaphthol is formed, which prevents the growth of staphylococci in dilutions of 1 in 250,000. Nevertheless, as internal antiseptics they are useless: they affect body tissues before parasites, and much of their antiseptic action is destroyed by tissue proteins.

If these coal-tar derivatives (cinamic acid, creosote, guaiacol, and the rest) exert a beneficial action on tuberculous patients, the explanation is not that they influence directly the tubercle bacillus. The same is, of course, true of formic aldehyde, at one time much in vogue as a vapour for inhalation by phthisical patients. Occasionally also it was injected intravenously, and not infrequently produced albuminuria, haematuria, and even coma. Formic aldehyde, of course, in the body at once combines with proteins and loses all antiseptic action.

\* The address was given to a meeting of the Tuberculosis Society at Cambridge on April 2nd.

## ESSENTIAL OILS.

Essential oils have been the basis of many systems of "cure"; thus the oil of cinnamon and oil of garlic treatments have each had its day; it were idle to describe them in detail, as it is universally recognized that, like other specifics, they fail in the hands of the sceptical physician. Fischer made numerous experiments on animals and showed, for example, that menthol eucalyptol injections into tuberculous rabbits in no way altered the course of the disease. *In vitro* such antiseptics as thymol and the cresols inhibit the growth of virulent human tubercle bacilli in strengths of 1 in 10,000, and these are the most active members of the group. Guaiacol and creosote only inhibit in strengths of 1 in 1,000, so that as bactericidal agents they are valueless.

## CALCIUM.

I will mention here two or three other substances which have been alleged to exert specific effects in tuberculosis, although not by direct destruction of the tubercle bacillus. Many have written on the beneficial action of calcium: thus Maendl treated 250 patients with intravenous injections of 5 c.cm. 10 per cent. calcium chloride every day or second day. The injections were given in alternate weeks, and each patient received twenty injections. All the symptoms were influenced favourably. Calcium deficiency is a well known condition of many diseases, including tuberculosis, and calcium injections may influence favourably the condition by limiting inflammatory exudation, but they do not influence the cause of the condition.

## SILICA.

Silica is another of these specifics of recent date. Maver and Wells, in a review of the literature on silica therapy, come to the conclusion that the beneficial effects described are not established. They made some experiments with silica casein metaphosphate on tuberculous guinea-pigs, but found no increase in the duration of life or alteration in the tuberculous process.

## ARSENIC AND MERCURY.

The employment of compounds of arsenic and mercury is particularly instructive because each new introduction has been described as being curative by one group of physicians and worthless by another. De Witt described certain mercury compounds which cause fibrosis and healing of tubercles in different organs in slowly progressing chronic tuberculosis of experimental origin. These effects were not seen in the control animals, however long they lived. Mercuri-bis-p-nitrophenol, and mono-ethyl-p-nitraniline mercury acetate were the compounds he used. The injections produced no nephritis in any animal. Inhalation of arsenic has been described as effecting cures by Chavant. On the other hand, careful experiments made with the likely organic arsenic derivatives such as arsphenamine and its silver compounds show that they have no action on the pathogenicity of the tubercle bacillus and no favourable influence on the disease.

## QUININE DERIVATIVES.

Chemotherapeutic agents have a specific selective action on certain tissues and bacteria, probably physical rather than chemical, and, unlike the group we have considered up to now, their disinfectant action is not retarded by admixture with serum, but, on the contrary, is increased. How selective these substances can be may be seen from one example. Atoxyl is a cure for syphilis like salvarsan, yet atoxyl is no longer used because it dissolves in the tissues of the eye and causes optic neuritis and atrophy, an effect which is not produced by either salvarsan or inorganic arsenic. After administering atoxyl to animals, arsenic is found in the humours of the eye, but no arsenic is present after administration of the other two substances.

Two groups of organic compounds are especially remarkable for their chemotherapeutic action on bacteria. Quinine is the methyl ether of cupreine, and it can be reduced by nascent hydrogen to form hydrocupreine. The following

table shows the effect of two derivatives of hydrocupreine in arresting the growth of certain micro-organisms.

	Ethyl Hydrocupreine (Optoquin).	Iso-octyl Hydrocupreine (Vuzin).
Diphtheria ...	1 in 100,000	1 in 750,000
Pneumococcus ..	1 in 400,000	Negligible
Staphylococcus .	1 in 500	1 in 16,000
Streptococcus ...	1 in 1,000	1 in 80,000

The action of optoquin on the pneumococcus and of vuzin on *B. diphtheriae* is absolutely specific; the higher and lower homologues do not exhibit this effect. Further, these drugs act in the animal body as well as in the test tube, and enough can be given by medicinal doses to animals and men to clear the blood from these micro-organisms.

#### ACRIDINE DERIVATIVES.

The second group of drugs which exert a marked action on bacteria are certain derivatives of acridine. Trypaflavine was used during the war for infected wounds; it acts better in the presence of protein, but is not sufficiently selective or specific on micro-organisms in the presence of body tissues to be of any real value; it is easily absorbed and causes oedema. Rivanol is a more recent derivative of acridine. Morgenroth cured streptococic infections in mice by injections of rivanol under the skin. The injections, to be efficient, must be made soon after infection and in the neighbourhood of the inoculated zone; rivanol will not cure a blood infection. Still its discovery is a great advance over any substance previously available, and we can look forward with some confidence in the near future to the introduction of new derivatives which will destroy acute infective agents.

The chemotherapeutical substances which are known to act on bacteria are without value in tuberculosis. Thus flavine and its silver salts do not influence the tuberculous process in living animals, and the same is true of the quinine derivatives which have been prepared so far. The destruction of the tubercle bacillus presents two special difficulties: (1) in the fatty and protective envelope surrounding the bacillus, and (2) in the small blood supply to the tuberculous lesions.

#### CERIUM.

Success, however, has been claimed for several metallic compounds, and I shall confine my remarks to three of these. The first is with cerium salts. Frouin experimented with fifty rabbits and thirty guinea-pigs; they were inoculated with bovine tuberculosis and treated by injections of cerium sulphate. All the animals died, treated as well as controls, but the treated animals survived from two to five months longer than the controls, and in *post-mortem* examinations showed considerable growth of fibrous tissue in the tuberculous lesions. Grenet and Drouin tried the effects of cerium earths in chronic tuberculous affections in patients. They state that two facts have been established—that these metals reduce the fats of the tubercle bacillus in cultures, and that they produce a mononuclear leucocytosis. Their procedure is to inject intravenously 2 to 5 c.cm. of a 2 per cent. solution for twenty days; this is succeeded by a period of rest for fifteen or twenty days, followed by a second and third series of injections. The patients improved in every way. The bacilli disappeared from the sputum, or if present were modified. Thus three of four guinea-pigs were inoculated with the infected sputum of treated patients; the guinea-pigs became sick and lost weight for two weeks, but at the end of two months they were normal again. These observers think the treatment of value only in afebrile cases. Renon and Esnault and Brou have confirmed these results, and also agree that in febrile cases the treatment is unsatisfactory. If cerium salts, including its allies, exert any action on tuberculosis it cannot be by direct action on the bacilli, since these salts and their compounds have little more direct action in killing the tubercle bacillus than potash salts. According

to the figures given, the inhibitory action is about 1 to 5 parts in 1,000 to prevent growth. On the basis of this slight inhibitory effect in cultures—and, what is perhaps more important, the production of leucocytosis—a small number of cases of human tuberculosis have been treated with cerium salts by repeated intravenous injections, and the patients have improved; but there is no mention of control patients given the same general care, without the salts. The evidence so far presented, however, is of little real significance. The fact that cerium has still its devotees in France is perhaps of some importance.

#### COPPER.

Copper salts have had a great boom in the past, though they have, at least for the time, lapsed into oblivion. Luton, in 1894, in a monograph, first drew attention to copper as a specific in tuberculosis. Grafm v. Linden and her colleagues in Germany produced a complex copper lecithin compound of secret composition; it was alleged to produce wonderful results in the treatment of patients. It is now more than twelve years since the introduction of this compound, and yet there is an alarming spread of tuberculosis in Germany, and since the war we hear little of the cure. Koga, in Japan, soon after v. Linden, produced cyanocuprol as a cure, but Koga's discovery has not settled the tuberculosis problem in Japan. The Japanese are very active in tuberculosis remedies; they have made many new compounds, sometimes of copper, sometimes gold, and sometimes other substances; but their tuberculosis does not diminish.

When the copper treatment commenced nearly all the reports were favourable to its use (Meissen, Strauss, etc.), but more extended investigations on animals made with the sulphate, oleate, albuminates, cyanocuprol and others have established the fact that so far as these salts are concerned the treatment, at all events on animals, is valueless. Schroeder, in particular, is definite that the copper treatment serves no useful purpose. Nevertheless, experiments with the putrefactive bacilli *Proteus vulgaris* and *Clostridium fetidum* show that copper salts are very strongly antiseptic; even when present to the extent of 1 in 2,000,000 a perceptible action is observed. Copper salts might be useful remedies in diseases characterized by increase of the number of putrefactive bacilli in the gastro-intestinal canal, particularly as they are not absorbed. They are also very active against the tubercle bacillus *in vitro*. Eggers showed that the influence of copper upon tuberculous tissues is strictly limited to a local effect; a deep and distant action is not obtained. On account of the increased susceptibility of the vascular nervous system around tuberculous tissues the action of the copper is greater in these than in normal tissues. He could not confirm von Linden. He states that true affinity of the copper for tubercle bacilli does not exist, nor could he find an affinity for tuberculous tissues; finally, the copper treatment of tuberculosis is not considered to be a specific therapy.

#### GOLD.

The last drug about which I propose to speak is the gold treatment. Koch showed that  $KAuCl_4$  (1 in 1,000,000) prevented the growth of tubercle in cultures; the presence of blood serum interfered with the action and reduced the efficiency to 1 in 25,000. Gold chloride inhibits when in dilution of 1 in 2,000,000; and yet, in the careful studies of De Witt, as in the earlier observations of Koch, it exerts no favourable influence on tuberculosis in animals.

Without reviewing the various papers dealing with this subject, I will sum them up by saying that the results of administering gold salts in tuberculosis were not better than those given by copper, whether on cultures of the tubercle bacillus, on tuberculous animals, or on patients.

Aurocyanan was next introduced; it is a cantharidin-ethylene diamino-aurocyanide, and was soon found to be too toxic for use. It was succeeded by a compound with a very promising composition, "krysolgan," introduced by Feldt. This compound prevents the growth of the tubercle

bacillus in cultures in 1 part in a million. Nevertheless, animal experiments with this substance are not very promising, though clinical results, as published in Feldt's monograph in 1923, are certainly both hopeful and inspiring.

The last of the gold cures is that recently introduced by Moellgaard.\* It is a double thiosulphate of gold and sodium,  $\text{Au}(\text{S}_2\text{O}_3)_2\text{Na}_2$ , which, although a well recognized substance, he calls sanoerysin. Like its predecessors it retards growth of the tubercle bacillus in glycerinated bouillon in such strengths as 1 part in a million, but how serum added to the cultures affects its action I did not discover. Nevertheless, this is a very important point, since such chemotherapeutic substances as exert an undoubted action on bacterin invariably act better in the presence of the tissue fluids. Moellgaard assumes that his gold injections destroy the tubercle bacillus *in vivo*, and states that doses which are not poisonous in themselves kill the tuberculous animal by producing a tuberculin shock. This shock begins with albuminuria and sometimes haematuria; it is followed by toxic myocarditis and pulmonary oedema. Non-tuberculous animals do not exhibit this shock.

The evidence to prove this important point is nowhere clearly set out—that is, that the shock in tuberculous animals after an injection of sanoerysin is due to the destruction of tubercle bacillus and the setting free of endotoxins, which act as tuberculin acts on tuberculous animals. To combat this shock Moellgaard recommends a previous injection of antitoxic serum, after which his gold cure may be injected with impunity. It would be interesting to know whether other metallic poisons cause a like shock.

Moellgaard made many experiments on calves, rabbits, and other animals to test his sanoerysin, and the treated calves certainly did better than the controls, and some of them recovered. His procedure was as follows: He injected a number of animals on the same occasion; after some days the animal which seemed least affected was chosen as a control. Dr. A. S. Griffith thinks that this was wrong, since the calves may have been infected before they were used for experiment. The injection of the tubercle bacillus would cause those which had acquired some increase of resisting power as the result of a spontaneous infection to react violently for perhaps a week, while the really susceptible animals would remain unaffected; one of the latter would be selected as the control. It is true Moellgaard made tuberculin tests when the animals were three weeks old, but their weights show that they were much older when injected. The experiments of Dr. L. Cobbett at Stansed under the Royal Commission showed that, in spite of ideal conditions and constant care, it was impossible to exclude spontaneous infection.

Another feature of importance in these experiments is that the cultures used were attenuated. The doses necessary to kill were enormous and many control animals failed to die or contract severe disease. The attenuation of the bacilli makes recovery much easier and the large size of the dose intensifies the severity of the reaction to injection in an animal already infected.

So far as I am able to judge of the value of the recorded experiments, they are suggestive, but certainly not conclusive. Some of the krysolgan and copper experiments on animals have been equally suggestive, and with regard to the patients it is early to draw conclusions; it is the opinion of those best able to judge that clinical records of treated patients must be kept for years before the true value of a remedy for tuberculosis can be gauged.

Sanoerysin, then, is still on its trial.

\* A paper by Professor Moellgaard on the theoretical basis of the sanoerysin treatment of tuberculosis was published in this JOURNAL on April 4th (p. 643).—Editor, BRITISH MEDICAL JOURNAL.

ON

## SOME FORMS OF VOMITING IN INFANCY.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, MARCH-APRIL, 1925,

BY

H. C. CAMERON, M.D.CAMBR., F.R.C.P.LOND.,  
PHYSICIAN IN CHARGE OF THE DEPARTMENT OF DISEASES OF CHILDREN,  
GUY'S HOSPITAL.

### LECTURE II.—VOMITING DUE TO OBSTRUCTION FROM NEUROMUSCULAR INCO-ORDINATION.

#### *Etiology.*

I COME now to consider the etiology of the second form of obstruction, that which depends primarily upon neuromuscular inco-ordination. The beautiful experiments of Bayliss and Starling have made clear the method by which a bolus of food is moved along the intestinal lumen. Excitation by the bolus produces a twofold reaction in the muscular tube—contraction in the segment above accompanied by relaxation in the segment below. The bolus, urged forward by the contracting muscles into the area of relaxation, thus evokes a succession of peristaltic waves which hurry it along the bowel. These peristaltic movements persist in an isolated loop of gut separated from its central nervous connexions. Nevertheless, the intestine is possessed of a double nerve supply which has the power of augmenting or of inhibiting intestinal tone and movement. The inhibiting fibres pass in the splanchnic nerves and peripheral stimulation produces cessation of movement and relaxation of tone. Stimulation of the vagus is less uniform in its effect, but most often after a short period of inhibition there follows a long phase of unusual activity of movement, and at times the gut may be so contracted as to obliterate its lumen.

Little is known of the localization of the cerebro-spinal centres of these two antagonistic sets of fibres. The centre for the inhibitory fibres is generally thought to lie in the spinal cord, in the upper dorsal and lower cervical regions. Yet Ott obtained inhibition by stimulating the optic thalami and cerebral peduncles. Budge and Valentin showed that intestinal movements could be excited and amplified by electrical stimulation of the corpora quadrigemina and corpora striata. Bochefontaine in Vulpian's laboratory obtained movements of the intestines of dogs by stimulating certain parts of the motor cerebral cortex. Our knowledge of the paths by which the higher centres influence the intestinal movements remains, however, doubtful, fragmentary, and contradictory. That emotional states are habitually accompanied by changes in the amplitude and frequency of intestinal movements is everyday experience. Cannon found that motor activity in the stomach and intestines of his cats lessened when the animals became excited or angry. Barclay, in studying the gastric tone and movement in normal individuals, describes the striking alterations produced by an unexpected stimulus such as a loud sound.

In considering the etiology of this group of disorders in infancy, characterized by a temporary failure of the inhibitory apparatus of the bowel, I put forward the hypothesis that in development the inhibitory apparatus is apt to lag behind the motor and augmentary apparatus. That at this early age we have to deal with an organism in which the inhibitory activities of the splanchnic nerves are functionally weak is suggested by a variety of considerations. It is perhaps to be expected that the supreme function of inhibition shall be that which is last acquired. In the case of the skeletal musculature a similar functional retardation of inhibition is the rule. The newborn infant, before the myelination of the pyramidal tracts, is rigid and spastic in all its movements. Until the cortex awakens and assumes control the infant is in a state of what might be called physiological diplegia. Only gradually does the power develop to relax antagonistic groups of muscles and to permit precise and effective voluntary movement.

It is interesting in this connexion that many observers have noted that hypertonus of the skeletal musculature is commonly more than usually marked in infants with congenital pyloric stenosis. Putzig has called attention to opisthotonos as an occasional symptom in hypertrophic pyloric stenosis. Feer has emphasized the characteristic set look of the facial muscles, showing especially in the wrinkling of the forehead. Certainly, in my experience, infants with hypertrophic pyloric stenosis, at least in the earlier stages, are more than usually tense, alert, and eager, with rigid limbs, exaggerated tendon reflexes, and clenched fists.

In certain degenerative disorders of the cerebrum we again meet with an increase of tonus in the skeletal muscles, with rigid limbs and stiff postures, and in such cases spastic states of the bowel musculature seem also unusually common. Here, as in many other conditions, there is a certain similarity between the results of functional weakness in the immature nervous system and disturbances directly due to degeneration and disease. In ascent and in descent, in development and in degeneration, the same country is traversed.

Thus I have at the present time a boy under my care in Guy's Hospital, 2 years of age. He belongs to a family more than one member of which has died of some obscure nervous disease in early childhood. In at least one of these it is known that optic atrophy was present. He is suffering from an unusual form of diffuse cerebral sclerosis, probably familial. Ophthalmoscopic examination shows the presence of optic atrophy, but no cherry-red spot such as is characteristic of amaurotic family idiocy. There is extreme rigidity of the limbs with pronounced opisthotonos. Through the rigid abdominal walls great waves of intestinal peristalsis are visible. There is extreme constipation. No motion is passed spontaneously, but by washing out the rectum hard scybala masses are removed from time to time. The colon is hypertrophied and can easily be felt through the abdominal wall. I show its outline as seen after an opaque meal, and after an opaque enema.

In this case it is clear that in an older child with cerebral degeneration hypertonus of the skeletal muscles and hypertonus of the intestinal muscles have developed together. In both the power of inhibition has been lost. I suggest that in the newborn infant, while a large part of the cerebrum is as yet functionless, there may at times be added to the lack of inhibition of skeletal musculature a similar weakness of the power to inhibit the splanchnic musculature. In the newly born, no doubt, the functional disturbance is often trivial, shading off by all gradations into the normal, and transient. In the similar conditions of later life the disturbance is often both severe and persistent. Of infantile achalasia at the cardia and pylorus it may be said that the time limits of the obstruction appear definite. In the case of the pylorus, certainly, if the infant does not succumb to intercurrent infection, recovery may be confidently predicted in the fourth or at latest the fifth month. The high mortality of this disease in the past has been due, not to the severity of the obstruction as such, but to the peculiar inability of the infant to withstand inanition and to the great fall in immunity which the inanition causes. Once the functional weakness at the pylorus has been overcome recovery never occurs. This certainty and this permanency of recovery are in keeping with the view that the symptoms are due to a retardation of functional development.

The failure of inhibition is, as might be expected, most evident at the site of the various sphincters, at the cardia, notably at the pylorus, at the ileo-caecal valve, and at the

ano-rectal sphincter. We owe to our President, I think, in the case of the cardia, the first enunciation of the conception that in a failure of relaxation of the ring muscle of the sphincter we have the primary cause of the obstruction. In 1896 Rolleston showed at a meeting of the Pathological Society a number of specimens of oesophageal obstruction, and put forward this hypothesis. More recently the radiographic studies of Hurst have afforded the proof of the correctness of the supposition, and he has coined the word "achalasia" to describe the condition. Under the x rays the failure of the cardia to relax is clearly evident, while *post-mortem* examination in these cases shows that, although there is hypertrophy of the walls of the dilated oesophagus above the obstruction, the ring muscle itself shows no trace of hypertrophy.

#### A. PYLORIC OBSTRUCTION.

The explanation

of the remarkable condition found in hypertrophic pyloric stenosis has been the subject of endless controversy. Armstrong in 1777 was probably the first to describe a case. In 1888 Hirschsprung of Copenhagen called the attention of the profession to the condition, describing the clinical symptoms with great accuracy, but erroneously regarding the cases as examples occurring in infancy of that congenital pyloric stenosis of Landereer and Maier described in the last lecture. The view that the obstruction at the pylorus is due to pressure from the bulk of muscle, the subject of a congenital hypertrophy, seems to me to have little to recommend it. Indeed, no true stenosis of the pyloric canal is present. Within the grip of the rigid musculature of the pyloric cylinder there lies a normal pyloric canal, its lumen in no way narrowed, but, as it presents itself at autopsy, so folded up that its outline is star-shaped or rosette-shaped upon transverse section. During life it is clear that the obstruction is not

FIG. 1.—Radiograph of adult stomach showing the shadow of the duodenal cap, a gap representing the pyloric ring sphincter, and the shadow of the lumen of the pyloric cylinder.

FIG. 2.—Diagrammatic representation of Fig. 1. D., Duodenal cap. P.R.S., Pyloric ring sphincter. P.C., Pyloric cylinder.

constant but intermittent. Hess and others have experienced little difficulty in passing a duodenal catheter even in the most severe case. During an operation, after the stomach has been opened, bougies of relatively large calibre can be readily passed from stomach to duodenum. There are several instances recorded (Stranch and others) in which foreign bodies of considerable size, accidentally swallowed during life, have been passed per rectum without difficulty.

We owe to Thomson the first enunciation of the more reasonable hypothesis of neuromuscular inco-ordination, against which the chief objection urged by Finkelstein, Marfan, and others is that it is difficult to understand why spasm and overaction of a sphincter should give rise to hypertrophy, upon so great a scale. In the light of our knowledge of the corresponding neuromuscular obstruction at the cardia, which we owe chiefly to Hurst, it would seem tempting to consider the hypothesis that we have here to deal with what he has named an achalasia—that is to say, with a primary failure of the pyloric sphincter to relax. In spite of Hurst's refusal in a recently published paper to accept this view, I venture to think that no other hypothesis fits so well with the facts as we know them.

If we examine a radiogram (Figs. 1 and 2) of the stomach and duodenum—and, since unfortunately in infancy the duodenal cap is never apparent as a distinct shadow, it becomes necessary to use a radiogram from an adult—we find the component parts well marked. The cardiac part of the stomach functions as a reservoir; the pyloric portion forms the so-called contractile cylinder. The pyloric portion of the stomach is described as consisting of a first part, the pyloric vestibule, which is

in general relaxed with a widely patent lumen, and the pyloric antrum (His) or the pyloric cylinder (Cunningham), the lumen of which in adults is also often widely patent, but which in the foetus and young infant after death is always obliterated by the rigid contraction of its thick muscular walls. The lumen of this pyloric cylinder is the pyloric canal. Radiographically between the duodenal cap and the shadow of the stomach adjoining is a gap less than  $1/4$  in. in length, traversed from time to time or continuously by a thread-like shadow. This gap represents the true pylorus occupied by the pyloric ring sphincter.

Now when we speak of a condition of congenital hypertrophic pyloric stenosis it seems to me that we employ a term which perpetuates at least three misunderstandings. In the first place, as has been said, there is no true stenosis present, only an infolding of the lumen when the hypertrophied walls of the pyloric cylinder are in a state of rigid contraction. In the second place, it seems to me that the hypertrophy certainly involves a great deal more than the true pylorus—that is, the pyloric ring sphincter. Indeed, I hope to produce histological evidence which goes to show that the ring muscle itself takes no part in the hypertrophy, but remains unchanged in its dimensions. The great hypertrophy is disposed along the whole length of the pyloric cylinder (Fig. 3), and extends to, and involves, the vestibule as well, gradually diminishing as the cardiac reservoir is approached. The tumour formed by the hypertrophied walls of the pyloric cylinder in the infant measures on an average about  $1\frac{1}{2}$  in. in length. If we are to assign all this length of hypertrophied muscle to the retaining mechanism of the stomach rather than to the expelling mechanism—

FIG. 3.—Outline of specimen of the left, and the thick-walled contractile cylinder between.

by the hypertrophied mass hardens and softens under the examining finger as each wave of peristalsis reaches it and fades away. This seems to me strange behaviour on the part of a sphincter, though readily understandable if the hypertrophy involves the walls of the contractile cylinder of the stomach and if the hypertrophied muscles are in intermittent contraction, endeavouring to force the contents of the stomach past an obstruction caused by the failure of the pyloric ring muscle to dilate.

Cunningham in his classical paper has made clear the disposition of the muscular coats of duodenum, pylorus, and stomach in the normal infant at birth. The sphincter is a well developed mass of muscle much thicker than the muscle of the wall of the rest of the pyloric cylinder. Into it passes the greater part of the longitudinal muscle fibres of the stomach coats spreading out within it as a fan-shaped fasciculus. It is this turning in of the longitudinal fibres which will enable us to identify the pyloric ring muscle proper in sections through the immensely hypertrophied muscles in so-called hypertrophic pyloric stenosis.

Cunningham, further, has a drawing of the muscular arrangement in the cat in which the sphincter proper is considerably more developed. This is of interest in view of Cannon's radiographical studies, which were carried out almost entirely on cats and which constantly show a widely dilated pyloric canal right up to the actual pylorus. Lastly, in a section which he shows through the muscle in a case of hypertrophic pyloric stenosis, it will be seen that the ring muscle is considerably less thick than the muscle of the pyloric cylinder behind it.

To compare with these illustrations from Cunningham's paper I show first a section through the pyloric region

FIG. 4.—Section through the pyloric region of a normal infant, aged 4 weeks. D, Duodenum. P.R.S., Pyloric ring sphincter. P.C., Pyloric cylinder.

FIG. 5.—A similar section through the pyloric region in an infant with hypertrophic pyloric stenosis. D, Duodenum. P.R.S., Pyloric ring sphincter of unchanged dimensions. P.C., Pyloric cylinder with greatly thickened musculature.

that is to say, if we are to regard it as a greatly hypertrophied sphincteric area of unusual length—the gap between stomach and duodenum would be radiographically represented by an hiatus, not  $1/4$  in., but  $1\frac{1}{2}$  in., in length. It is unfortunate that the absence of the duodenal cap in infants prevents this gap from being appreciable or measurable. It seems to me that a study of the *post-mortem* appearances shows clearly enough that the hypertrophy involves the whole contractile cylinder, which alone has peristaltic activity and the property of projecting the food forcibly through the narrow pylorus into the duodenum. Only the cardiac portion, which functions as a reservoir and which shows no peristalsis but peristole, escapes or almost escapes hypertrophy. In life nothing is more remarkable than the way in which the tumour formed

of a normal infant, aged 4 weeks (Fig. 4). Again the ring muscle is much the thickest part and can be clearly identified by the turning inwards of the longitudinal fibres. In the next slide (Fig. 5) we see the condition in hypertrophic pyloric stenosis under the same magnification. The sphincter, identified as before by the passing inward of the dilator longitudinal fibres, which are here very considerably hypertrophied, is now very much thinner on cross-section than the immensely thick wall of the pyloric cylinder which lies immediately to the stomach side of it. The last section, also from a case of hypertrophic pyloric stenosis, shows the same appearance, although in this case the sphincter muscle is overlapped by and appears almost imbedded in the hypertrophied muscle of the wall of the pyloric cylinder.

I think it may be said that the histological evidence is not opposed to the view that in hypertrophic pyloric stenosis we have to deal with an achalasia of the pyloric ring muscle and that the hypertrophy involves, not the sphincter, but the contractile cylinder—that it is a hypertrophy of muscle devoted, not to the retaining apparatus of the stomach, but to the expelling apparatus. If so, the histological evidence is in agreement with the macroscopic appearances and with the clear clinical evidence of peristaltic activity in the palpable muscle mass.

The third mistake which is perpetuated in the commonly accepted name is involved in the description "congenital." If it is clear that there is no stenosis and no hypertrophy of the pylorus, it is equally clear that the condition is not congenital. Only one observer, Dent, has reported this condition in a foetus. I think it possible that he

stomach of the normal size. I believe that in this photograph, which has caught the contractile cylinder in a phase of relaxation, we have outlined the enormous lumen which after death is completely obliterated, just as an autopsy may disclose a thick-walled bladder, tightly contracted, and without any considerable lumen, which during life was subject at times to enormous distension.

In discussing the etiology of hypertrophic stenosis it is necessary to consider at the same time a group of cases in which obstruction at the pylorus is present in equal degree yet without hypertrophy of the contractile cylinder. The pyloric part of the stomach, instead of forming a cylindrical tumour of hard whitish muscle, is absolutely flaccid and shows no evidence of gross hypertrophy of its walls. Such cases are described as suffering, not from pyloric hypertrophy, but from pyloric spasm. Clinicians who have submitted to operation a large number of cases of pyloric obstruction in infancy almost without exception record the same experience. In a very small percentage of the cases the laparotomy discloses, not the expected hypertrophy, but its unexpected absence. Finkelstein, a most careful and acute observer, for long contended that a condition of persistent and almost complete closure of the pylorus without hypertrophy did not exist. Lately, as a result of an experience such as I have described, he has more than once expressed his altered view. He now regards the mistake as inevitable in a small proportion of cases. It

is true that in very many, though not in all, cases with hypertrophy the pyloric tumour is readily palpable, but the separation of the two groups cannot be made upon the strength of this one point alone. Not only are there cases with hypertrophy in which the tumour is persistently impalpable—at times it is situated high under cover of the liver margin—but there is often little difficulty in feeling a normal pyloric cylinder in systole, provided that the abdominal wall of the infant is sufficiently lax.

Persistent and severe pyloric obstruction, with visible gastric peristalsis upon a great scale, with inanition stools and collapsed and empty intestines, yet without hypertrophy, is rarely encountered. Very many of the cases described in the literature as examples of pyloric spasm are in reality instances of other types of habitual vomiting, which I shall consider in the next lecture. In my own experience, among 32 cases of pyloric obstruction submitted to laparotomy, the hypertrophy was unmistakable in 30. Twice only was its absence disclosed. The first of these cases occurred in 1912, the second quite recently.

J. S., aged 7 weeks, was admitted to Guy's Hospital in November, 1924—a thin, eager, alert infant, with a striking degree of muscular rigidity. His weight at birth was not known; on admission it was 6 lb. 12 oz. The mother thought he had lost a great deal of weight. Throughout he had been breast-fed. During the first eleven days of life he had made satisfactory progress. On the eleventh day vomiting began, and had occurred without exception after every meal. The most careful questioning of the mother failed to shake her evidence on this point. The vomiting was violent and explosive in character. It never occurred during nursing, but always within half an hour, usually within a few minutes, after its completion. The infant was very restless, constantly crying, and ravenously hungry. For many weeks a little dark-green pigmented material had been removed every few days. In the void gastric peristalsis was clearly visible, two right waves being present simultaneously, passing from left to right across the epigastrium. The pylorus could not be felt. The state of the child was such that I asked Mr. Hughes to operate at once, expecting to find the usual hypertrophy of the pyloric cylinder on which a Ramstedt operation might be performed.

FIG. 6.—A, The normal stomach. B, In hypertrophic pyloric stenosis—an early case with slight enlargement of the contractile cylinder. C, In hypertrophic pyloric stenosis—a late case with great enlargement of the contractile cylinder.

may have mistaken the pyloric cylinder normal condition with which he was familiar. If the disorder were truly congenital, its frequency is so considerable that it is inconceivable that examples should not be forthcoming from among infants submitted to autopsy within the first weeks of life. In general the appearance of symptoms is delayed for some weeks after birth—usually from two to four weeks. Even when vomiting has begun and is persisting with all its characteristic violence, the evidence of hypertrophy is not immediately available. It appears only after an interval and steadily increases so long as the obstruction persists unchanged. The contractile phases are variable. Periods of exaggerated activity and increased peristalsis in the hypertrophied contractile cylinder are succeeded by periods of exhaustion and calm. Visible peristalsis, a stomach which is easily palpable and which may stand out prominently under the abdominal wall, a pyloric cylinder which can be felt as a veritable tumour, hardening and relaxing under the finger, are symptoms encountered only after some weeks of more or less persistent obstruction. The typical x-ray appearances, as shown diagrammatically in Fig. 6, also develop slowly. Fig. 7 shows the appearance on the fourth day after the first act of vomiting and on the fifteenth day of life. Clinically, no pyloric tumour was then palpable, and the evidence of visible peristalsis was slight. Radiographically the contraction cylinder is slightly enlarged with active peristalsis. Operation on the same day showed a moderate degree of hypertrophy of the muscular wall. Yet for four days preceding operation vomiting had been very violent, the weight had fallen rapidly, and the stools had become dark-coloured and slimy. In contrast with this early case, Fig. 8 shows the stomach, at the end of the fourth month of life, from an infant in which severe symptoms had been continuously present since the third week. In this case I had no operation performed, because it appeared likely, as indeed soon proved to be the case, that spontaneous recovery was imminent. The contraction cylinder shadow is enormously enlarged; the rest of the

FIG. 7.—Radiograph showing slight enlargement of the contractile cylinder. From an early case.

FIG. 8.—"Enormous" enlargement of the contractile cylinder. From a late case.

The stomach was large and distended, the pyloric end quite flaccid and free from any hypertrophy. The small and large intestines were nilko collapsed, empty, and of strikingly small calibre.

Because of the clear evidence that a state of pyloric obstruction had long existed, I asked Mr. Hughes to cut through the pyloric ring musculature down to the mucous membrane but without prolonging the incision backwards on to the pyloric antrum, as in a Ramstedt operation. The true pyloric valve muscle and that only was severed. From the moment of section of the pyloric ring the child was never sick again. Feeding was begun at once, and the amounts given were rapidly increased. On the fifth day after the operation the child had three breast feeds in no way limited, and four feeds of a milk, water, and sugar mixture. The stools within twenty-four hours of the operation became normal in colour and consistency.

I do not wish to deduce too much from a single case, but the observations made upon this infant do very strikingly support the hypothesis that the symptoms were due to an achalasia of the pyloric valve, and that the distinction between pyloric hypertrophy and pyloric spasm is not fundamental, as, indeed, was always maintained by Holt in America. In both, achalasia of the pyloric ring muscle is the primary cause of the spasm and increased tonus of the gastric musculature. In all but a minority of the cases hypertrophy of the walls of the contractile cylinder of the stomach is gradually added as a secondary feature. It may be that the reason for the absence of hypertrophy in a few instances is to be found in the case with which in these particular cases the food escapes through the cardiac orifice. In the case which I have just quoted the regularity and severity of the vomiting was quite unusual, and might have served to awaken the doubt as to whether hypertrophy was present. It is possible that hypertrophy is only produced when, as is more usual, the escape by the cardia is only achieved with difficulty, when the stomach retains its contents for many hours, and sometimes even for days, and when phases of violent and exaggerated peristaltic activity in the effort to overcome the obstruction are prolonged. After spontaneous recovery from all symptoms the pyloric tumour for long remains palpable, and the peristalsis may remain visible for months, or even years. Numerous autopsies upon children who had formerly suffered from pyloric stenosis have disclosed the persistent hypertrophy of the pyloric cylinder. Since hypertrophy often persists long after the cessation of all symptoms, and since symptoms of great severity and typical in character may occur without hypertrophy, it would appear necessary to presume the presence of a primary achalasia in all cases.

It remains to consider one further point. Will simple section of the pyloric ring muscle at once relieve the symptoms in a case with typical hypertrophy, or must the incision be prolonged backwards over the pyloric canal to sever the whole hypertrophied circular coat of the contractile cylinder?

I have hesitated to put this matter to the test in an individual case because it is clear that the vomiting is not due only to the failure of the pyloric ring muscle to open. The explosive character of the vomiting is determined, not by the pyloric obstruction alone, but also by the gastric hypertrophy and spasm. In purely organic stenosis the vomiting is never so violent, nor is there produced the picture of the spastic stomach with its outline clearly visible beneath the abdominal wall. Sometimes, indeed, the spasm extends to the pharyngeal muscles, so that during the height of the exaggerated gastric activity the infant may be unable to swallow. It is highly significant that there are a few autopsies upon record which have disclosed hypertrophy of the lower end of the oesophagus as well as of the contractile cylinder, presumably a combination of cardiac and pyloric achalasia. Thus, for example, Pritchard, in 1920, at the Royal Society of Medicine exhibited a specimen with hypertrophy of the lower end of the oesophagus, and hypertrophy of the "ileo-caecal sphincter" combined with hypertrophic pyloric stenosis. In this disorder of the innervation of the gastric musculature neither the failure of the pyloric ring muscle to open nor the spasm of the hypertrophied contractile cylinder above it is of itself sufficient to account for the symptoms. Both must be present at the same time. Both are parts of the same disturbance in the production of the syn-

chronous contraction above and relaxation below which together make up the peristaltic wave. The presence of a sphincter in any situation in the bowel does not alter this primary relationship between contraction and relaxation, although functionally it may throw a greater emphasis upon the movement of relaxation. In this disorder of peristalsis it seems a mistake to lay emphasis solely on the excessive contraction or solely on the failure of relaxation. Both phases are involved. Only if we can imagine a peripheral stimulus going out from the ring muscle itself can we conclude that it would be sufficient to divide that alone in order to do away with the spastic contracture at the higher level. If this were to prove the case, then the Ramstedt operation, simple and successful as it is in the great majority of cases, would be still further simplified, because complete incision of the mass of hypertrophied muscle would no longer be needed and the risk of haemorrhage would be reduced to a minimum.

If it is tempting to hypothesize a uniform cause for all these infantile disorders marked by inco-ordination of the gastro-intestinal musculature and to regard all as accompanied by achalasia of the several sphincters, we must not at the same time lose sight of the difference between the local conditions prevailing at each site. Behind the pyloric sphincter, but not behind the cardiac, is a segment of the gut which has a highly evolved propulsive mechanism. Above the cardia, in achalasia of that sphincter, the hypertrophy is slight, perhaps even at times inappreciable, because the pressure within the oesophagus is low and the cardia opens in response to a minimal stimulus. In the oesophagus, as in the auricle of the heart after death, dilatation rather than hypertrophy is a prominent feature; in the thick-walled contractile cylinder of the stomach, as in the main propulsive chamber of the heart, the ventricle, it is the hypertrophy which is most obvious. It is possible that simple section of the ring muscle may suffice at the cardia, yet fail at the pylorus.

The view that the primary cause of the spastic obstruction of the pylorus is due to a primary hyperaesthesia of the mucous membrane with an accompanying excessive secretion of gastric juice seems disproved by the immediate success of the muscle-splitting operation. The secretory changes would appear to be secondary to the disorder of innervation.

#### B. OBSTRUCTION AT THE ILEO-CAECAL VALVE.

At the ileo-caecal valve it appears likely that in early infancy a similar failure to inhibit the ring musculature is occasionally met with. In the following case an achalasia of the ileo-caecal valve was apparently combined with some degree of anal achalasia.

K. McD. was seen by me in Guy's Hospital on the ninth day of life. For the first three days after birth nothing abnormal had been noticed, although less meconium than usual had been passed. Vomiting began on the fourth day, and from the fifth day onwards had been continuous. The vomited matter was stained with bile. On that day, the fifth of life, he was admitted to hospital. An x-ray examination after a barium meal showed only a trivial delay of the barium in the duodenum. Within ten minutes it was seen in the jejunum. In the ward, between the fifth and the ninth days, when I first saw him, vomiting of bile-stained fluid had taken place on several occasions, but the most striking symptom was the obstinate refusal of the bowels to act, in spite of the prescription of various purgatives, such as hydr. cum cret., castor oil, and finally pituitary extract hypodermically. Enemata of soap and water had likewise failed of effect, until on the ninth day an olive-oil enema had produced the passage of a very small amount of yellow faecal material. Since the early passage of meconium in the first days of life nothing had been passed in the interval. On this, the ninth, day I saw the child. The abdomen was moderately distended, and there were visible peristaltic waves, apparently of the small intestine. On the twelfth day a second x-ray examination was made to ascertain what had become of the barium taken on the fifth day. I show the radiogram. The colon is considerably distended, although perhaps the distension is most apparent in that part which is empty of barium and distended only with gas. The dilated coils of small intestine distended with gas and containing a little barium are also apparent. Rectal examination showed nothing abnormal, but on exposing the abdomen the visible peristalsis in the small intestine was now very striking, the whole contour being broken into a series of ridges and furrows. The bowels were slightly open during this examination, and flatus was passed freely.

Confronted by this situation it was difficult to know how to act. Since the visible peristalsis appeared to be due to the small and

not to the large intestine, the diagnosis of Hirschsprung's disease appeared to be unlikely. On the other hand, the presence of the barium, so long stationary in the colon, appeared to exclude any obstruction in the ileum.

Since the general condition of the child had steadily deteriorated and much weight had been lost, at my request Mr. Steward performed a laparotomy. At once very greatly thickened and hypertrophied coils of small intestine presented in the wound. Much of small intestine had to be allowed to escape from the abdomen before it was possible to trace this hypertrophied gut to the neighbourhood of the ileo-caecal valve, where, at a point about one inch above the caecum, the calibre suddenly narrowed and the congestion marked above gave place to a paler colour. The caecum and first part of the ascending colon appeared considerably distended. There was no sign of obstruction by a band or by a diverticulum. With considerable difficulty the intestines were replaced and the abdominal wall sutured. The child at first seemed little the worse for the operation. Hypodermic injections of atropine sulphate gr. 1/500, at four-hourly intervals, were given without appreciable benefit. The bowels were open once after the operation, but the distension steadily increased, and the child died four days after the operation. No *post-mortem* examination was permitted.

The case can, I think, only be explained on the assumption of an achalasia of the ileo-caecal valve with secondary spasm and hypertrophy of the bowel above, combined with a similar, though less marked, achalasia of the anal sphincter. In the literature few similar cases have been described, at least in early infancy. I can refer only to the paper by Wilms on persistent intestinal spasm, and to an exhibit before the Anatomical Society of Paris by Gaikler and Nau of three foetuses, each with multiple spastic strictures of the intestine. I have notes of one other similar case seen with Mr. Hughes, in which the thickened small intestine was both visible and palpable. The baby was sent to me from the West Norwood Maternity Home on the fourth day of life, with bilious vomiting, abdominal distension, and extreme constipation. From the tenth day onwards recovery gradually took place.

#### C. OBSTRUCTION AT THE ANUS AND IN THE RECTUM.

The etiology of Hirschsprung's disease, like that of hypertrophic stenosis, has been greatly discussed. Hale-White, Fenwick, and Hawkins in this country have upheld the view that neuromuscular inco-ordination in some particular segment of the bowel is responsible. Two groups of cases are described. In that which is most characteristic, and to which the name "Hirschsprung's disease" should perhaps be confined, the symptoms of absolute constipation and abdominal distension date from birth. There may be difficulty even in the passage of meconium. In a well marked case the symptoms are developed in a quite characteristic way before the child is more than a few days old. I show a photograph taken in the *post-mortem* room of an infant at one time under my care, who died on the tenth day of life in Guy's Hospital; also the photograph of an older child, aged 3 years. The great distension of the abdomen, through the wall of which the peristalsis of the hypertrophied colon was clearly visible, is well shown. Of the first case I was not able to get a satisfactory x-ray plate, but of the second case I show the shadow of the huge colon in its lower part outlined by means of a bi-monthly enema. The dilatation passes downwards to the anal sphincter itself. With such a shadow there can be no question of the dilatation and hypertrophy being a secondary result of obstruction by organic stenosis of the bowel or by kinks, acute angles, or spurs. In three other cases, which I have had the opportunity of examining in early childhood, the same picture—the extension to the anus itself—has been seen. It is clear that the cause must be found in a failure of relaxation in the anal sphincter. In other cases the achalasia may affect the other sphincters described by Keith in the rectum and sigmoid. Behring and Klercker have recently reviewed the literature and brought forward additional proof of the origin of Hirschsprung's disease in localized *Kontraktionsringen* with resulting secondary changes. In a second group of cases, which show the syndrome of Hirschsprung's disease, the origin is probably different. As a rule, the onset of symptoms is delayed until later life. Many show acute angular kinks of the colon, with adhesions between adjoining loops of the bowel or with the lumen, large as it is, partially

occluded by infolded spurs or valves. These doubtless are secondary effects resulting from many causes and perpetuating the obstruction. It is possible that some cases which in early infancy were examples of anal or rectal achalasia with secondary hypertrophy, distension, and elongation of the colon, may pass gradually into the second category, and that the symptoms may be perpetuated by secondary organic obstruction due to acute kinking of the bowel with spur formation long after the infantile lack of co-ordination has been overcome. In other adult cases achalasia may be the result, not of developmental delay as in infancy, but of degenerative changes in the central nervous system involving the higher central connexions of the inhibitory paths. In the recorded cases a disproportionately large number appear to have been encountered in idiots.

#### D. OBSTRUCTION AT THE CARDIA.

Beck and Göppert have both described carefully observed cases of temporary dysphagia in infants due to so-called "cardiospasm."

In Beck's case the infant was a male, aged 3 months. The regurgitation of milk in an unchanged condition, and quite unmixt with stomach contents, was the main symptom. Milk introduced directly into the stomach was never vomited. The act of swallowing was clearly involved, and there was much gurgling and choking. A sound encountered an easily overborne obstruction 15 cm. from the gums. At the height of the disturbance there was a loss of weight of 400 grams. The disturbance lasted for two months, when complete and permanent recovery took place. In a second case, also reported by Beck, the duration was shorter—four weeks.

Göppert had a similar experience. In the first of his cases, however, complete recovery did not take place until the ninth month of life. Hess, in passing his duodenal catheter in newly born or very young infants, noted that there is not infrequently some slight obstruction, easily overborne, encountered at the cardiac orifice.

It is probable that in the infant whose diet is wholly fluid obstruction at the cardiac sphincter is too intermittent and too easily overcome commonly to give rise to persistent symptoms such as Beck and Göppert have described in exceptional cases. Persistent cardiac achalasia of adult type is not infrequently found in young children, but not, I think, in infancy.

# THE EFFECT OF ANTISYPHILITIC TREATMENT, AS GAUGED BY THE SIGMA REACTION.

BY

P. H. JONES, B.A., M.D., D.PHIL. OXON.

(From the Department of Pathology, University of Oxford.)

APART from their diagnostic value, the Wassermann reaction and the more recent flocculation reactions have assumed a position of importance as guides in the treatment of syphilis. It is well known that the blood and cerebro-spinal fluid may give a positive reaction long after the clinical signs of active syphilis have disappeared, and although Hess Thaysen<sup>1</sup> believes that in certain cases a positive reaction does not indicate active syphilis, it is very generally held that a positive reaction in the blood or cerebro-spinal fluid is a sign of active syphilis and therefore an indication for treatment (Boas,<sup>2</sup> Fordyce,<sup>3</sup> Osler and McCrae<sup>4</sup>).

In view, then, of the prevailing opinion that the ultimate goal of antisiphilitic treatment is a permanent negative reaction, it was proposed to investigate how far the present methods of treatment are effective in attaining this end, or at any rate in reducing the amount of reacting substance in the blood during a certain period of observation. In order to carry out this investigation, it was clear that the blood of each patient would have to be examined at fairly frequent intervals, and that the results of the examinations would have to be quantitative and comparable with one another. In the opinion of the authors (Dreyer and Ward<sup>5</sup>) the Sigma reaction gives more strictly comparable results than the quantitative Wassermann reaction. Madsen,<sup>6</sup> Renaux,<sup>7</sup> Wyler,<sup>8</sup> and Houston<sup>9</sup> found the Sigma reaction quantitatively accurate. Madsen gives the result of titrating four syphilitic serums by means of the Wassermann reaction. Each serum was titrated fifty times, 200 titrations in all being carried out:

85 titrations gave	0 per cent. deviation from average.
85 " " " $\pm 33$ " " "	
20 " " " $\pm 60$ " " "	
10 " " " $\pm 78$ " " "	

In other words, the Wassermann reaction gave an average deviation of  $\pm 24$  per cent.

At the same time 109 titrations were made on ten serums by means of the Sigma reaction, and the greatest deviation observed did not exceed  $\pm 6$  per cent.

Hirzfeld,<sup>7</sup> however, found that the Sigma reaction does not give a sharp end-point, and he found it difficult to calculate the real strength of the serum. In the present investigation incomplete flocculation, of the kind observed by him, has not been a source of difficulty, the end-point of the titration being always well defined.

With regard to its sensitiveness and specificity Dreyer and Ward<sup>5</sup> stated in their original communication that the Sigma reaction had in their hands yielded results that compared more than favourably with the Wassermann reaction. The support given to this claim by subsequent investigators may be judged from the following comparative tests carried out by the International Health Organization of the League of Nations.\*

\*At the time of writing the above the results of the last League of Nations conference at Copenhagen at the end of 1923 were not available. At this conference 536 serums were tested simultaneously by the different methods for the diagnosis of syphilis. The Wassermann reaction yielded a greater number of positive reactions than the Sigma reaction. This result was in striking contrast to the results previously obtained by the same workers, and was investigated by Dr. Mörk. He found that the Sigma reaction had been rendered less sensitive by three details in the technique: (1) the heart extract supplied had been given too low a factor of sensitiveness; (2) the serums had been inactivated in hermetically sealed tubes (that is, under pressure) instead of in tubes with a cotton-wool stopper; (3) the tests had been incubated in a semiclosed water-bath instead of an open one. In some cases this reduced the number of units by some 500 per cent. When these details had been corrected it was still found that the cases of dementia paralytica which had been treated with malaria were more active in the complement fixation than in the flocculation system. This phenomenon is being further investigated.

TABLE I.—Diagnostic Results.

Name.	Cases of Syphilis.			Controls.		
	No.	Wassermann Reaction Positive.	Sigma Reaction Positive.	No.	Wassermann Reaction Positive.	Sigma Reaction Positive.
Dreyer <i>et al.</i> <sup>5</sup>	519	Per cent. 62.0	Per cent. 69.4	203	No. 5	No. 7
Madsen <sup>7</sup>	627	59.3	77.7	885	0	6†
Harrison <sup>7</sup>	498	51.0*	57.8	244	14	20‡
Hirzfeld <sup>7</sup>	358	51.0	50.3	61	0	0
Müller <sup>7</sup>	1357	68.5	60.5	340	0	0
Renaux <sup>7</sup>	189	55.5	74.6	100	0	2
Sachs <sup>7</sup>	404	54.5*	51.5	576	3	3

\* Including doubtful Wassermann reactions.

† Three of these cases later diagnosed as syphilis.

‡ Eleven of these cases later diagnosed as syphilis.

The Sigma reaction, then, seemed to lend itself very well to the kind of investigation that was contemplated—namely, the study of the quantitative changes that took place in the blood of syphilitic patients over an extended period of time.

## PREVIOUS INVESTIGATION OF THE EFFECT OF TREATMENT. AS GAUGED BY FLOCCULATION REACTIONS.

Vernes<sup>10</sup> has devised two somewhat complicated methods for determining the flocculating power of the serum in cases of syphilis, the results being expressed quantitatively. He has further formulated certain rules for diagnosis and cure.<sup>11</sup> Lortat Jacob and P. Legrain<sup>12</sup> found Vernes's second method less sensitive than the Wassermann reaction, and the results of a comparative test by Vernes himself<sup>10</sup> indicate that his second method is less sensitive though more specific than the Wassermann reaction. The scale used by Vernes in expressing his results is so different from that used in the Sigma reaction that it would be difficult, if not impossible, to compare his results with those obtained by workers using the Sigma reaction. Houston and others<sup>9</sup> employed the Sigma reaction to study the effect of treatment in 170 cases of syphilis. They found: (1) that in general the Sigma units fell during treatment with arsenical preparations, when effective doses were used, and that a study of the results of the reaction gave considerable help in determining the effective dose and the effective interval between doses; (2) that the rate of fall in units in tertiary cases of syphilis was much slower than in primary and secondary cases; (3) that there was a certain amount of evidence that mercury, intramine, and potassium iodide have less effect than the arsenical preparations in lowering the Sigma units; (4) that a negative Sigma reaction does not necessarily mean that the case has been cured.

Stokes and Wigham<sup>13</sup> observed the effect of treatment on about fifty cases of syphilis, also by means of the Sigma reaction. They found that the primary and secondary cases, when treated at regular intervals with arsenic, showed a fairly steady and continuous fall in Sigma units; but among tertiary cases they did not see one react satisfactorily during the period of observation, the curve of Sigma units in the blood showing only ups and downs.

## THE PRESENT INVESTIGATION.

In the present investigation the effect of treatment upon the Sigma units in the blood of 138 cases of syphilis was observed both during courses of treatment and during varying periods following these courses. The cases were in three clinics, and while in most of the cases the ordinary routine of treatment in the clinic was not interfered with, in certain special cases, through the kindness of the directors of the clinic, changes were made.

The majority of the patients received intravenous injections of novarsenobillon (N.A.B.) at weekly intervals, and the patients were also given mercury pills (Hutchinson's pill) with instructions to take two daily. A course of injections of N.A.B. was followed in some instances by a course of intramuscular injections of mercury (1 c.cm. of

grey oil). In a few cases sulfarsenol and sodium silver novarsenobillon were used, as Harrison<sup>13</sup> has stated that these preparations gave encouraging results in cases with myocardial and nervous lesions.

In certain cases in which the arsenical preparations seemed to have little or no effect on the serological reaction, injections of mercury perchloride were given intravenously. The technique of Conrad and McCann<sup>14</sup> was followed, 1.2 to 4 c.cm. of a 1/2 per cent. solution of mercury perchloride in saline being injected. In order to prevent thrombosis of the vein, the patient's blood and the solution are mixed in the syringe before injection. They found that after from six to twenty-two injections, 64 per cent. of a series of sixty-two "Wassermann-fast" cases gave a negative Wassermann reaction. In the present series of cases it was only possible to give one injection a week, instead of twice a week as advocated by Conrad and McCann.

#### TECHNIQUE AND EXPERIMENTAL VARIATIONS OF THE SIGMA REACTION.

The technique described by Dreyer and Ward<sup>5</sup> and supplemented<sup>6</sup> was followed throughout, the results being read after an incubation period of twenty hours.

The amount of experimental variation was investigated by testing portions of the same specimen of serum many times. The flocculation readings varied from day to day, but repeated themselves frequently, the mean deviation being 6.7 per cent., while the standard deviation was 9.5 per cent.

The cause of these variations was chiefly the fluctuations in temperature of the water-baths in which the inactivation of the serum and the incubation of the tests were carried out. An additional cause was the reading error of the different degrees of flocculation, and this was found to be greater in strong serums than in weak, small irregularities in the flocculation tending to occur in the high dilutions of the serum, probably owing to the small amount of protective serum-protein present.

In addition to the above, another cause of variation was noted. Two alcoholic heart extracts which had been used for a period of five months showed a sudden deterioration in the sensitiveness of their suspensions. The amount of this was determined, and the errors due to it were corrected. The sudden deterioration was probably due to the fact that these particular heart extracts had been prepared by making a more concentrated extract of the heart muscle than that described.<sup>6</sup> The other heart extracts used showed no change in sensitiveness, and the stability of the heart extract which was used during the greater part of the investigation was established by an extensive series of tests. Chart 5 shows a case which was followed over a period of fifty weeks. During this period the number of Sigma units found only varied between 5.0 and 4.1. This and similar cases confirm the belief that, despite experimental variations, the unit values obtained in testing a serum from time to time are really comparable. It remains to determine the limit of the experimental variation.

It was stated above that the standard deviation found was 9.5 per cent. In a series of determinations the probable error of a single determination is about two-thirds of the standard deviation—that is, 6.3 per cent.—and the probable limit of experimental variation would be approximately 20 per cent.<sup>15</sup> Accordingly, unless there was a 20 per cent. change in the unit value of a patient's serum, it was not considered to be a real change in the serum of that patient.

The number of Sigma units varied widely in different patients—from one unit to over two thousand units; and in order to correlate the results in different patients the changes in the Sigma units of a given patient were expressed in percentage.

#### EFFECT OF ARSENICAL INJECTIONS.

##### I. Upon Patients whose Blood gave a Negative Sigma Reaction before Treatment commenced.

In this connexion, three questions arise:

1. Can the injection of arsenical preparations in definitely non-syphilitic cases induce a positive reaction in the blood? Strickler and others<sup>16</sup> administered one or more injections of neo-arsphenamin (neosalvarsan) to twenty-four

patients in whom there was no sign of syphilis and who all had negative Wassermann reactions prior to the injections. Fourteen of these twenty-four patients—that is, 58 per cent.—gave two or more positive Wassermann reactions after the injections. Boas and Kissmeyer,<sup>17</sup> however, found that the injection of salvarsan or its derivatives into fifty non-syphilitic cases did not induce a single positive reaction. In the present investigation only one definitely non-syphilitic case received injections of arsenic, and the Sigma reaction remained negative.

2. Can the arsenical preparations light up a case of latent syphilis and change the reaction from negative to positive? There is a fairly widespread belief that in certain cases of suspected or latent syphilis with a negative Wassermann reaction the injection of a so-called "provocative" dose of arsenic will light up the syphilitic inflammation, and the blood of the patient will subsequently give a positive Wassermann reaction, confirming in this way the tentative diagnosis. In the light of the experience of Strickler and others,<sup>16</sup> this "provocative" Wassermann reaction must be treated with reserve. In the present study, three cases with a history of syphilis or a history of a positive Wassermann reaction in the past, but who had a negative Sigma reaction at the time the injections began, were given several doses of N.A.B. All three cases remained negative.

3. What is the prognosis of cases of primary syphilis which give a negative Sigma reaction at the commencement of treatment and remain negative during the course of treatment? Two such cases were observed, and they remained negative subsequent to the course of treatment. So far as this limited evidence goes the prognosis is favourable, thus confirming the evidence afforded in similar cases by the Wassermann reaction. In this connexion one case (Chart 1) is of interest. The case was one of suspected primary syphilis; spirochaetes were not demonstrated, but one week after treatment commenced 1.4 Sigma units were found in the blood. This figure, though not quite high enough to warrant a definite diagnosis of syphilis, aroused further suspicion, and the treatment was continued; the number of units fell to normal and remained there. The diagnosis must remain doubtful if (according to the scale laid down by the authors of the reaction)<sup>6</sup> an unknown case must have at least 1.5 Sigma units in the blood to establish the diagnosis. But, of course, in such a case it is much better from the patient's point of view to be on the safe side, and treat the case as one of syphilis, rather than suspend treatment and wait to see if the reaction becomes definitely positive.

##### II. Upon Sigma-positive Primary Cases and Secondary Cases.

In the course of the investigation twenty-two such cases were observed. These cases respond more uniformly to treatment than cases in the later stages of the disease, and the following points were noted:

1. In about one-third of the cases a rise in units was found just after treatment commenced. The units then fell. This preliminary rise must be regarded as the expression of the normal evolution of the disease, which has only been partially checked by the first injections of arsenic. Chart 2 shows the curve of a case of this kind.

2. The main response in these cases was a continuous fall in the number of Sigma units during the serial injections, the fall becoming slower as the number of units approached 1 (a non-syphilitic case may show as much as 0.9 Sigma unit in the blood). Chart 3 shows a typical response to regular treatment in this stage of the disease, in this case without any well marked preliminary rise in units. The rate of fall in the number of units is of interest. In nine primary and early secondary cases, one week after each injection, the number of units had fallen on the average to half the number of units present before the injection; on the other hand, in eight late secondary cases, one week after each injection, the number of units had only fallen on the average to two-thirds the number of units present before the injection. In other words, the rate of fall is definitely slower in the late cases in this group.

CHART 1.—Case of suspected primary syphilis, showing what are probably early serological changes and the response to treatment.

CHART 2.—Case of secondary syphilis, showing the abortive rise noted in about one-third of the early cases.

CHART 3.—Case of secondary syphilis. This case became negative in the shortest time of any early cases. Treatment was regular.

CHART 4.—Case of primary syphilis showing first a rapid fall with treatment, then stationary after a lapse and a rise after a second lapse.

CHART 5.—A tertiary case which showed throughout the observation a continuous fall in units.

CHART 6.—A latent case which was stationary before treatment; showed a fall during the first course N.A.B., none during the second, and then showed a fall during the course of intravenous HgCl<sub>2</sub>.

CHART 7.—A tertiary case which improved three times during treatment, and relapsed three times during non-attendance. The formation of a gummata occurred six months after a reading of only 3 units.

3. The evidence concerning the relation of the amount of N.A.B. received and the response by the patient is suggestive but not very definite, other factors coming in to obscure the picture. Eight cases became negative after receiving an average of 6.9 grams of N.A.B. (seven of these cases remained negative up to the end of the period of observation), while fourteen cases did not become negative after receiving an average of 4.4 grams of N.A.B. However, among the cases which did not become negative, there were three which received as much N.A.B. as the cases which did become negative. In these resistant cases, however, other factors, such as irregularity of attendance, incomplete treatment, came in.

4. It had been previously noted by Stokes and Wigham that a break in the course of treatment might have a definitely prejudicial effect when treatment was resumed, the cases becoming resistant to arsenic, although previous to the break in treatment their units had been falling. In this series of cases there were four in which the Sigma units were falling steadily under treatment with N.A.B., and then there was a period of four weeks during which they received no arsenic. In two of these cases a further fall in units occurred when treatment was resumed, and one case eventually became negative. In the other two cases subsequent treatment seemed to have little effect, and indeed the units commenced to rise again after the cessation of the second series of injections with arsenic. Chart 4 shows the Sigma curve of one of these cases, and brings out very clearly the danger of breaking off the arsenical treatment of early cases before the blood gives a negative Sigma reaction. In this connexion Chart 4, showing the result of irregular and incomplete treatment, should be compared with Chart 3, where the course of treatment was regular and complete. If patients in the early stages of syphilis could be shown such charts as these it would encourage them to attend the clinic regularly for treatment. Patients in this stage of the disease are sometimes apt to regard themselves as cured when their active signs—sore, rash, etc.—have disappeared, and they attend irregularly in consequence. But if their intelligent interest in what is being done for them is aroused by charts such as these, they would be more likely to become regular attendants. The case represented by Chart 3 was shown his Sigma curve, and became keenly interested in the progress of his cure.

5. In seven cases, one injection of metallic mercury was given at the end of a course of arsenic injections, and a fall in units occurred after the mercury injection in all these cases. In four out of the seven cases the reaction became negative without further treatment. However, since in five out of the seven cases the mercury injection was given one week after the last injection of N.A.B., the fall in units cannot be ascribed entirely to the effect of the mercury. One case in the series became intolerant to arsenic when he still had 1.1 Sigma units in his blood. Six intravenous injections of mercury perchloride were given, and three weeks after the last injection his units had risen to 67. The evidence, then, as far as it goes, is in favour of the use of metallic mercury, but against the use of mercuric chloride in this stage.

### III. Upon Tertiary Cases.

In the 106 tertiary cases which were investigated, the response to treatment was much slower and much less uniform than in the early cases. The following points were noted.

1. Out of the 106 cases three only became negative while under observation. The details of these cases are:

CASE I.—A case of latent syphilis which had previously received 16.2 grams of N.A.B. and nine injections of grey oil over a period of 156 weeks. At the beginning of the present treatment there were 1.7 Sigma units in the blood, and the reaction became negative after two weeks' treatment with 1.2 grams of N.A.B. Subsequent history unknown.

CASE II.—A case of angina which had previously received 16.2 grams of N.A.B. over a period of 130 weeks. At the beginning of the present treatment there were 3 Sigma units in the blood, and the reaction became negative after twenty weeks' treatment with 4.8 grams of N.A.B. Subsequently, injections of mercury perchloride were given, and the reaction was still negative at the end of a further period of nineteen weeks.

CASE III.—A case of glossitis which had previously received 6 grams of N.A.B. and six injections of grey oil over a period of

forty-three weeks. At the beginning of the present treatment there were 1.8 Sigma units in the blood, and the reaction became negative after six weeks' treatment with 5.1 grams of N.A.B. Subsequent history unknown.

It will be noticed that these three cases had all received a good deal of treatment previous to the present investigation, and they all had a low Sigma unitage at the commencement of the present treatment.

2. In three cases there was a definite rise in units during the period of observation. In two of these cases there was definite clinical evidence of increased activity of the disease. Chart 8 shows one of these cases. In the remaining case there were no symptoms or clinical signs at all during any period of the observation. The evidence thus suggests that a rise in units is associated with an increased activity of the disease.

3. The remaining cases in this group apparently responded to treatment in three ways: (1) The number of units fell steadily during the period of observation. Chart 6 is an example of this type, which may be called the "falling" type of response. (2) The number of units remained practically unchanged during the period of observation. Chart 5 is an example of this type, which may be called the "stationary" type of response. (3) The number of units fell for a variable period and then remained stationary. Chart 7 is an example of this type of response, which may be called the "plateau" type.

These differences in response to treatment are probably more apparent than real. It must be remembered that the tertiary stage of syphilis is a very long one, and that these cases came under observation at different periods, after different treatment, and were only under observation for a time (at most two years), which was short compared to the length of the tertiary stage. It is probable from the evidence obtained in this investigation that, unless there are exacerbations in the disease, the amount of reacting substance in the blood in the tertiary stage remains practically unchanged over a long period. Sometimes the amount of this substance cannot be influenced by treatment—there were a certain number of cases which remained stationary although they had had no previous treatment. In the majority of cases, however, it can be reduced, but eventually takes up a new level which is uninfluenced by further treatment. In a small proportion of cases the reaction may become negative, but the conditions under which this occurs are obscure. Probably if a continuous fall to a stable negative is to be produced with any certainty it can only be accomplished by an extensive and prolonged effort, using methods more effective than those of the present investigation.

The point at which the amount of reacting substance in the blood becomes relatively stationary varies widely, although it is rarely above 50 Sigma units, and in the majority of cases below 15 Sigma units. There appear to be several factors which influence the level at which the units tend to become stationary, and these will now be reviewed.

(i) *Novarsenobillon* (N.A.B.).—This was used in the majority of cases. Three cases showed a rise in unitage, but of the remaining 90 cases approximately two out of every three cases showed some degree of fall in unitage. It may be remarked that the 58 cases whose units fell during treatment came under observation with a higher average unitage (131 Sigma units) than the average unitage (44 Sigma units) of the 32 cases which remained stationary under treatment.

*Sodium Silver Novarsenobillon* ( $\text{NaAgN.A.B.}$ ).—This was used in 6 cases with nervous lesions and one other case whose chart is shown—Chart 5. Here there was no change in units, although 3.2 grams were injected in all. Of the 6 cases with nervous lesions, the units were reduced in 4 cases, but 1 case remained stationary, and 1 case showed a rise in units. This result, however, may be considered more satisfactory than the result of treating cases with nervous lesions with N.A.B., where, of 9 cases, 3 only showed a fall in units and 6 remained stationary.

*Sulfarsenol* was given in 5 cases only, and although the units fell in 4 cases out of 5 the reduction was not very striking.

**Mercuric Perchloride.**—Intravenous injections were given to 24 cases, in all of which the number of units had been stationary for some time before this method of treatment was begun. Each patient received approximately 0.1 gram of  $\text{HgCl}_2$  in all, spread over about ten injections. In 13 cases, the number of units remained unchanged, and in 11 there was an average fall of 25 per cent. in the unitage. This result is apparently not so good as that claimed by Conrad and McCann,<sup>14</sup> who, however, gave their injections twice instead of once a week and gave more injections than were given in this investigation.

**Other Drugs.**—No attempt has been made here to distinguish the effect of the mercury pills which were given at the same time as the arsenical preparations, and often between courses of arsenic. During intervals between courses of arsenic, 29 cases were given potassium iodide in 10-grain doses for an average period of six weeks; in 5 cases the number of units had risen at the end of this period, and in 24 cases the unitage remained unchanged.

(ii) **The Effect of Rest.**—In the majority of the tertiary cases observed there was a period of rest during which no treatment was given. In about 90 per cent. of the cases no change in the units was found; in the remainder there was a rise in 5 per cent. and a fall in units in 5 per cent.

(iii) **The Size of the Injection Dose of N.A.B.**—The effect of this can be studied in the following table:

TABLE II.

Dose.	Stationary Cases.			Falling Cases.		
	No. of Cases.	Percentage of Total Cases.	Average Amount of N.A.B.	No. of Cases.	Percentage of Total Cases.	Average Amount of N.A.B.
0.3 gram	2	2.2	Grams. 2.7	—	—	—
0.45 "	10	11.4	3.8	10	11.4	9.4
0.6 "	9	10.2	6.8	27	30.6	6.3
0.9 "	11	12.5	4.0	19	21.6	4.7

It would appear from this table that 0.9 gram is the most effective dose of N.A.B., because of the relatively large proportion receiving this dose who showed a fall in units, despite the fact that they received on the average much less N.A.B.

(iv) **Interval between Doses.**—Fourteen cases received one injection at a time at irregular intervals, varying from three weeks to six months. These injections had no effect on the number of units. Subsequently 8 cases out of the 14 received a course of weekly injections, and 5 out of these 8 cases showed a substantial fall in units. However, in 2 cases where this fall was observed, the condition was not stable, and the units rose to the previous level after a period of rest.

(v) **Previous Treatment.**—Fifty-five out of the 106 cases had received at least one course of injections before coming under observation, and these were for the most part less responsive to treatment than those who had received no previous treatment.

4. The "provocative" effect of an injection of N.A.B. in tertiary syphilis. In a certain number of cases there had been no arsenical injection given within two months of the beginning of the observation, and in these the number of Sigma units was noted before and one week after the first injection of N.A.B. No "provocative" rise in units was observed.

#### RELATION BETWEEN THE NUMBER OF SIGMA UNITS AND THE ACTIVITY OF THE DISEASE.

This is a very difficult question, because it is impossible to determine clinically the exact extent of the disease—for example, the clinician cannot ascertain during life syphilitic changes going on in the aorta, although extensive disease is frequently seen *post mortem*.

However, in this connexion, certain cases with lesions of

the mouth and skin were studied. In these the exact extent of at least one lesion could be determined. It was found that although there was a tendency for cases with more extensive lesions to have a higher number of units in the blood, the number of units increased out of proportion to the visible evidences of the disease. For instance, three cases with ulcers of the mouth averaged 6.6 Sigma units, and three cases, with ulcers of the mouth probably twice as extensive, averaged 300 Sigma units. As the units seemed to increase out of proportion to the visible lesions, one must suppose that either the cases with higher units had undisclosed lesions, or that an additional and unknown factor was operative.

In this study the findings of one case with inflammation of the mouth and fauces is of particular interest. This patient (Chart 8) had three courses of treatment, during which he improved clinically and his Sigma units fell steadily. He did not attend the clinic between the courses of treatment, and when he did return his condition was definitely worse clinically and his units had risen. The third eyele was marked by the formation of a gumma during a six months' absence from the clinic. His units had risen then from 3 to 225. When treatment was recommenced and the gumma broke down into an open ulceration, the units dropped to 71.

#### THE RELATION OF CLINICAL IMPROVEMENT TO SEROLOGICAL IMPROVEMENT.

Although a detailed study of this kind was beyond the scope of this investigation, certain general observations were made. Table III summarizes 75 cases. It does not include either the latent or the early cases.

TABLE III.—Relation of Clinical and Serological Improvement.

Sigma Units.	Definite Improvement.		Doubtful Improvement.		Stationary.		Worse.	
	No. of Cases.	Percentage of Total Cases.	No. of Cases.	Percentage of Total Cases.	No. of Cases.	Percentage of Total Cases.	No. of Cases.	Percentage of Total Cases.
Falling ..	33	43.0	9	11.8	3	4.0	0	0
Stationary	12	15.8	7	9.2	8	10.5	1	1.3
Rising ...	0	0	0	0	0	0	2	2.7

This table shows that clinical improvement was far more frequent in cases which showed a fall in units than in cases which did not. Also, in cases which became worse clinically, the units either rose or remained stationary.

#### SUMMARY AND CONCLUSIONS.

In summarizing the results of this investigation it may be said that—

##### 1. As regards technique:

By means of the Sigma reaction it was possible to estimate with a high degree of accuracy the amount of reacting substance in the serum of cases of syphilis, the probable error of any single determination being about 6 per cent. The evidence for this is based on the result of many tests on the same specimen of serum on different occasions, and many tests on the serum of certain patients at different times.

Evidence of the same type confirms the claim that properly prepared heart extracts are stable in regard to sensitiveness.

##### 2. As regards the effect of treatment on the number of Sigma units in the blood in the early stages:

In the early cases of syphilis which gave a positive reaction at the beginning of the observation, one-third showed an abortive rise at the commencement of treatment. In these cases after the rise was over, and in the remaining two-thirds of the cases each arsenical injection produced an average fall of 42 per cent. in the number of units present before that injection.

Cases which attended regularly and had a full course of treatment showed in general a steady fall in units to a stable negative reaction, but cases which attended regularly and had an incomplete course of treatment were liable to become resistant to arsenic, the number of units often remaining stationary when treatment was resumed.

3. As regards the effect of treatment in the tertiary stage:

Only 3 out of 106 cases became negative; at the beginning of observation these cases had a low number of units, and had received much previous treatment. Of the remaining cases the units fell in about one-fifth of the cases, fell and then remained unchanged in one-third of the cases, and remained unchanged throughout in one-third.

In 3 cases a rise of units was observed, and in 2 of these cases the rise was associated with a visible increased activity of the disease.

It is probable that in the majority of tertiary cases the Sigma units fall to a certain level as a result of treatment and that it is difficult to cause a further fall in units. This level is usually between 2 and 15 Sigma units.

The most effective dose of N.A.B. was 0.9 gram. No substantial effect was observed in the number of units, if the injections of N.A.B. were given at intervals of three weeks or longer.

Intravenous injections of mercuric perchloride were given to 24 stationary cases, and produced a fall in units in about 50 per cent. of these, but no case became negative.

About 90 per cent. of cases showed no change in their unitage during rest or during oral treatment following courses of N.A.B. The remaining 10 per cent. showed a rise and fall of units in equal proportions.

The number of units in the blood corresponds to a certain degree with the visible extent of the activity of the disease. In 43 per cent. of cases a fall of units was associated with clinical improvement, but in 15.6 per cent. the units remained unchanged, although there was improvement clinically.

I desire to express my grateful acknowledgement for the kindly assistance that has made possible this work, and my great appreciation to Professor Georges Dreyer and Dr. H. K. Ward of the Department of Pathology, University of Oxford, for much assistance and advice.

I wish to thank for their great kindness and most substantial help Dr. J. H. Sequeira and Dr. W. J. O'Donovan of the London Hospital, who supplied me with a large amount of material; also Dr. P. Fildes of the London Hospital for the Wassermann results on this material; also Dr. A. G. Gibson, Mr. H. A. B. Whitelocke, and Dr. W. T. Collier, jun., all of the Radcliffe Infirmary, Oxford, for the use of their clinical material and records.

My particular thanks are due to Dr. F. G. Hobson of the Radcliffe Infirmary, Oxford, for the use of his clinical material and great co-operation in prosecuting the research.

My special thanks are due to Miss J. Jorgensen and Dr. A. D. Gardner of the Department of Pathology, University of Oxford, for their generous help in many points of the work.

## CARCINOMA OF THE RECTUM COMPLICATED BY PREGNANCY.

## TWO CASES TREATED BY EXCISION.\*

BY

R. CHARLES B. MAUNSELL, F.R.C.S.I.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND; SENIOR SURGEON TO MERCER'S HOSPITAL.

DURING the past three years I have had the uncommon experience of operating upon two patients for the removal of carcinoma of the rectum during the period of gestation.

## CASE I.

Mrs. B., aged 27, was admitted to Mercer's Hospital on January 4th, 1922. She had one child, aged 12 months, and stated that during the past five months she had had pain when the bowels moved; the pain had been much worse recently and sometimes she lost a quantity of blood; her weight had declined considerably.

A ring-like stricture of the rectum was found about the level of the cervix uteri; it was extremely painful, but with care the index finger could be passed through its lumen. The sensation given to the examining finger was that of a malignant growth. Upon bimanual examination of the pelvis the growth appeared to be freely movable, but the disconcerting fact was discovered that the uterus corresponded, in size and consistency, to a pregnancy of between three and four months' duration. No proctoscopic examination was made, as the parts were extremely tender and the diagnosis was obvious. The facts were fully explained to the patient and to her husband, and radical operation was decided upon.

Owing to the difficulty of clearing the bowels it was decided to perform a preliminary colostomy. On January 10th an incision, about four and a half inches long, was made through the left rectus muscle, at the junction of the middle and outer thirds, the pelvis and abdominal cavity were manually explored to exclude secondary growths, and a permanent colostomy opening was made, taking care to leave plenty of colon below the point of fixation. The protruding knuckle of gut was opened and trimmed before the patient left the operation table. Three weeks later, when she felt and looked much stronger, the cecum and last segment of the sacrum were removed and the entire rectum and anus, together with the sphincters and the greater part of the levatores ani, were excised in one piece. The cut end of the pelvic colon was then closed by suture, invaginated, and fixed extraperitoneally. The wound was closed in two layers; a drainage tube being inserted rather posterior to the site of the original anal opening. There was very little loss of blood and no shock. The drainage tube was removed on the third day, sutures were removed on the eighth day, and the patient was allowed up on the twentieth day after operation. The pathologist's report was: "Columnar-celled carcinoma of the rectum."

The pregnancy progressed along normal lines, and in the following June the patient entered the Rotunda Hospital. I am much indebted to Dr. J. Quinn, one of the assistants to the Master of the Rotunda, for the following particulars:

"Mrs. B., aged 27, was delivered, on June 28th, 1922, of a healthy male child, 18 in. long and 6½ lb. in weight. Labour lasted sixteen hours, placental stage thirty-four minutes. No instruments were used. There was a very slight laceration of the perineum, which was repaired immediately. The chief feature of the case was the absolutely normal manner in which labour progressed and terminated."

Shortly afterwards Mrs. B. and her family went to live in England, and I have lost sight of her.

The second case was diagnosed accurately and sent to me by Dr. B. H. Farrell of Castleconier on January 14th, 1924.

## CASE II.

Mrs. K., aged 38, had had nine living children, and on the date mentioned thought that she was three months pregnant. For the past seven months she had been very constipated, and an increasing amount of mucus and blood had come from the bowel, until the discharge was almost continuous. She had very little pain, and did not think that she had lost much weight, but was very depressed. On examination a friable fungating mass was felt surrounding the lumen of the rectum just above the level of the cervix uteri. Bimanual examination revealed a three months' pregnancy and almost certain involvement of the cervix, as the growth and cervix appeared to move together. At first I refused radical operation, and a colostomy did not appear necessary; but the absolutely miserable and hopeless condition of the patient made me alter my opinion, and I told her that I would, if necessary, remove the rectum and uterus.

I wrote a very full account of the risks and of the almost hopeless prognosis to Dr. Farrell, so that he might explain matters to the patient's husband, who gave me a free hand to do anything which might relieve her wretched condition.

On January 22nd, assisted by the house-surgeon, Dr. Mervyn Abrahamson, I opened the abdomen in the middle line below the umbilicus, examined the liver and iliac glands, etc.; then, having tilted the table into the full Trendelenburg position, I drew the uterus out of the pelvis and found, to my great relief, that it

\* Paper read before the Royal Academy of Medicine in Ireland, November 14th, 1924.

## HAEMOLYTIC STREPTOCOCCAL INFECTION.

[THE BRITISH MEDICAL JOURNAL 827]

was not involved in the growth, but was adherent to the rectum and could be separated from it by sponging with a gauze pad. The iliac colon was then divided, the proximal end brought out through an incision in the left rectus, and a Paul's tube tied in. The pelvic colon and rectum were then separated from the pelvis, along with all glands and areolar tissue, packed from the pelvis, removed, along with the anus and muscles, by the perineal route. The only points in which this operation differed from that described by many surgeons is that, owing to the encroachment of the pregnant uterus, I could not divide the middle haemorrhoidal arteries and lateral ligaments of the rectum by the abdominal route, and had to leave them to be dealt with during the perineal portion of the operation. During the perineal dissection I removed a portion of the tumour. The loss of blood was small and shock so slight that it did not need any special treatment. Convalescence was uneventful, and the patient was allowed up on the sixteenth day after operation, as she was still very depressed, and lying in bed seemed to make her worse. The pathologist's report was: "Columnar-celled carcinoma of the rectum."

On November 8th Dr. Farrell very kindly sent me the following note:

"Mrs. K. returned home about a month after operation. She had gradually got back strength and every day improved in health. On June 30th she slipped and fell in her kitchen. About half an hour after the fall signs of labour set in and lasted for twelve hours without result, when she was given an injection of pituitary extract which, almost immediately, resulted in the birth of a small living male child. There was no trouble with the placenta. This is her tenth baby and he is still alive. Mrs. K. is now doing well, says she never felt better in her life, is increasing in weight, and has a good appetite. The artificial anus is doing splendidly. She thinks that she is pregnant again."

The anaesthetic used in both these cases was ether, administered from a wide-bore Clover's inhaler.

As is well known to most surgeons, there are two "schools" of rectal surgery. One advocates the perineal route for excision, the other despises anything except the combined abdominal and perineal operation.

In the first case I made use of the perineal route, with preliminary exploration and colostomy, because I had no reason to suspect involvement of the uterus, etc., and I considered that the two-stage operation would be less severe on the patient.

In the second case I made use of the combined method, because I meant to remove the uterus and appendages, it necessary, and also because, owing to the depressed state of the patient's mind, I did not think she would consent to a two-stage operation. One cannot expect to operate upon a sufficient number of such cases to enable one to draw up statistics, but the lesson which I have learnt from these two cases is that the two-stage operation is much easier, and I think it should be the method chosen in cases where pregnancy is a complication, unless there is some special reason for the one-stage operation.

Before passing on to more problematical subjects, I would like to state my personal opinion that the incision through the left rectus is the best for colostomy, either with or without a median incision for the exploration. There is no need to defer opening and trimming the knuckle of gut, as there is no fear of infecting the wound or wounds if a covering of bismuth and iodoform paste is applied under a separate dressing. In the one-stage operation it is obvious that a Paul's tube can be tied in.

With regard to the treatment of carcinoma of the rectum in general, I sometimes use the combined method, and more often the perineal, with removal of the coecum and the last segment of the sacrum, a thorough exploration and a colostomy opening having been made some days previously.

I am convinced that the mortality of the combined method is very much greater than that of the two-stage operation, and I am not convinced that the percentage of "cures" is much more by one method than by the other, provided a preliminary exploration is insisted upon in every case. To put the matter shortly, in order to elicit dissection, I may state the teaching which I give to students. When the growth is in the portion of the bowel which has no mesentery, remove it by the two-stage method, unless there are glands high up which one has to remove. When the growth is situated higher up it is better to remove it by the combined method. I will not describe the steps of the operation performed, but for combined operation will refer to the beautifully illustrated description by the late Edward H. Taylor in his *Operative Surgery* (1914), and for the perineal method I cannot improve upon the

technique described by Mr. J. P. Lockhart-Mummery in the *Medical Annual* for 1924. In the latter method I find that working from the anal region upwards is much easier than the older method of freeing the rectum above before excising the anus.

The question—whether it is ever advisable to preserve the anal sphincters—remains. I have been much struck by the following paragraph in E. H. Taylor's book already mentioned, which shows the opinion he held before 1914. "The radical measures which are employed in the treatment of rectal cancer have as their object the complete removal of the disease and the re-establishment of normal sphincteric control." In 1924 the majority of surgeons appear to favour a permanent colostomy and sacrifice the sphincters in every case. Whether this is right or wrong I have not yet had sufficient experience to decide, but I feel that to eradicate the disease is the main thing, and that striving after sphincteric control may lead to inefficient operations.

## HAEMOLYTIC STREPTOCOCCAL INFECTION: RECOVERY.

BY  
ARTHUR F. COLE, F.R.C.S. EDIN.,  
WEST MALLING, KENT.

In view of the fact that in both medical and lay circles conversation often ranges upon the utter failure or tremendous success of dental extractions in certain systemic infections, this case, carefully followed by a number of observers, should be of interest. As a problem in diagnosis it exercised many, and its happy termination does not prevent one from thinking over the possibility of better methods of treatment, and, above all, earlier diagnosis in similar cases of pyrexia of unknown origin.

On November 6th, 1921, Michael R., aged 19, a student of medicine at Cambridge, complained of malaise and anorexia and fever, followed twelve days later by jaundice and gradual recovery. On November 28th he had a rigor, with violent headache, a temperature of 105°, and profuse sweating simulating malaria. He resumed his studies, and nine days later had his third attack. He a further rigor, high temperature, etc., and pains in the hepatic region. Blood examination excluded malaria, and showed a leucocytosis of 15,000 per c.mm.—polymorphs 84 per cent., lymphocytes 12 per cent., hyalines 4 per cent. After two further attacks of a similar type, showing almost identical differential leucocytosis, he was seen by Sir Humphry Rolleston. Cholecystitis was diagnosed, and hexamine and salicylates prescribed, with dieting. A fortnight later the seventh attack showed an increased leucocytosis and the polymorphs rose to 87 per cent. of the total.

Specimens of urine and faeces were examined by Dr. P. J. Cammidge on February 1st, 1922, and found fairly normal, though the latter contained coliforms and streptococci; he diagnosed catarrh of upper intestine, with secondary cholangitis and hepatitis. The next attack was accompanied by more marked hepatic pain and an easily palpable spleen, and Sir Humphry Rolleston again saw the case; he found a submucosal haematoma, half an inch in diameter, on the pharyngeal wall. During the apyrexial interval following the blood was again examined: Total leucocytes 6,000 per c.mm.—polymorphs 46 per cent., lymphocytes 50 per cent., hyalines 4 per cent. A catheter specimen of urine was sterile.

The patient was seen again on March 5th. He had been looking seedy for some days, and on this day the right side of the face was slightly swollen, but there was not the slightest pain in face or teeth. It was suggested that there might be a septic focus in face or neck to be in perfect repair, and had been recently overhauled by the dentist. Shortly after midday the ninth attack commenced, with hepatic pain, high temperature, and rigor; the spleen was still palpable and tender. A blood film showed nothing abnormal; leucocyte count 11,400; differential not done. Blood cultures were taken during this attack; both plates and broth remained sterile.

On March 16th an x-ray examination by Dr. Charles A. Clark showed both antra quite clear, but the second right upper premolar was a dead tooth with much swollen periodontal membrane and bone destruction at apex, indicating a chronic abscess. Twelve days later the tenth rigor occurred with hepatic pain and sweating; there was slight fullness of the right side of the face, but no pain in the teeth. It was decided to remove the suspected upper premolar as a likely focus of sepsis.

On March 30th the tooth was very carefully removed under nitrous oxide and from the injected root cultures were taken on agar and blood serum. The former remained sterile; the latter gave "almost pure culture of haemolytic streptococci." On April 10th and 14th an autologous vaccine (streptococcal) was given in 2 and

4 minim  
about 4.2  
followed  
splenic  
swollen.  
A leucocyte count showed 26,000 per c.mm.—polymorphs 81.5 per cent., lymphocytes 10 per cent., transitionals 8.5 per cent. On the question whether the above attack was similar to previous attacks the patient was emphatic that it was quite different; on the question as to whether the vaccine treatment was the cause, the long delay in onset (thirty-one hours) after the last injection was considered by Sir Almroth Wright to be somewhat against this theory, even if the doses had been too close together. About this time Dr. A. L. Punch of Brompton Hospital tested the blood by the complement fixation method for tuberculosis and found it negative.

On May 22nd he developed measles at Cambridge, twenty-eight days after leaving home. Subsequently he was operated on by Mr. Sidney Scott, F.R.C.S., for acute otitis media, and the lateral sinus had to be explored.

On July 8th diplopia developed. Mr. Holmes Spicer, F.R.C.S., reported homonymous hemianopia and convergent strabismus about 20 degrees, mainly left eye. There was no apparent diminution of movements in either eye. There was severe optic neuritis of the right eye and many retinal haemorrhages: the retinal veins were very full and tortuous. In the left eye the disc was highly coloured, the veins were full, and there was one haemorrhage on the nasal side of the optic disc. The right optic neuritis was still present on July 17th, but subsiding.

On October 2nd the right optic disc was still seen with plus four lens; the haemorrhages had all gone—a few dots remained outside the optic disc. Dr. Henry Cotton of University College Hospital made a thorough examination of the heart: he found it was slightly enlarged but within normal limits; there was no evidence of any valvular disease, past or present. He considered the prognosis good. Further radiographic examination was made by Dr. W. C. Long of Tunbridge Wells, with special reference to lungs, liver, and face. Nothing abnormal was discovered.

When seen in March, 1925, the patient seemed in perfect health and was engaged in medical study. He had put on a stone in weight, and was keen on athletic exercise. It is now three and a half years since his severe illness commenced, and during the last two and a half years he has been in normal health.

So far as one can see, the patient has overcome the very severe infection by a haemolytic streptococcus, twice isolated in almost pure culture—first from the dental root abscess, then from the mastoid discharge; the presence of streptococci in faeces may also have been connected with the marked hepatic and other symptoms which led to the opinion that there was an inflammation of the upper intestinal tract. Apparently no permanent organic change has taken place, though there is still a slight enlargement of both heart and spleen. It seems reasonable to consider the turning point to have been the extraction of an infected tooth which had given no trouble, and which the dentist had considered healthy a short time previously. Although blood culture during one of the acute attacks was negative, it is probable that streptococci were in the circulation at some period, and the extension to the meninges evidenced by the optic neuritis and strabismus makes the complete recovery of the patient all the more noteworthy, and should be an encouragement to those treating similar cases.

What, then, was the factor or factors which led to the triumph of the body defences? Most will allow that the removal of a septic focus was necessary; but how difficult to find in some cases, and how easy it is to be wise after the event! Drugs probably had very little influence. Secondly, a factor in recovery was the natural vaccine therapy of the body; this was either continuously in operation, or at those crises when rigors and high temperatures occurred—ten during four and a half months. Whether the few injections of autogenous vaccine helped or hindered is a question; in the matter of dosage and intervals between doses upon which Sir Almroth Wright has taught and is teaching, one realizes that Nature may be hindered instead of helped. The method of immunotransfusion, in which the blood of a suitable and healthy individual treated by vaccines is then transferred to the circulation of the patient, would seem to be ideal for such acute and anxious cases as this.

Finally, it is possible that clinical observations are correct in suggesting that one disease may oust another. Incompatibilities may exist between diseases; the onset of measles in this case may have been the decisive factor in determining recovery from a streptococcal infection so often fatal. Compare the effect of artificially produced tertian malaria upon the progress of general paralysis of the insane, and the effect of induced abscess formation upon kala-azar in the pre-antimony tartrate injection period.

Note by Sir W. H. Wilcox, K.C.I.E., M.D.

The case described is of very great interest. The symptoms pointed clearly to a septicaemic infection of focal origin. The recurring attacks of rigors and high temperatures were undoubtedly due to recurring invasions of the blood stream with pathogenic organisms. The jaundice occurring early in the attack was no doubt due to a hepatitis resulting from the septic invasion. It seems clear that in this case the primary focus was an apical dental infection of the second right upper premolar, which was disclosed by x-ray examination of the teeth. A point of great interest is the relative increase in the lymphocyte count (50 per cent.) on February 19th, 1922, associated with a total leucocyte count of 6,000 per c.mm. (a slight leucopenia). I have often observed this phenomenon in cases of chronic septicaemia of dental origin. The organism seems to have been a haemolytic streptococcus associated with the apical dental infection, and the severe reaction after the autogenous vaccine confirms this view. The eradication of the primary focus of sepsis marked an important improvement in the patient's condition and the recurring rigors ceased—in other words, the big septicaemic invasions were stopped.

In cases of this type the removal of the primary focus of infection, if it is of long standing as in this case, is not necessarily followed by complete cure, because secondary smaller foci have probably become established in the bowel or elsewhere. In this case it is probable that this secondary infection was the result of the otitis media following the attack of measles. The inoculations probably played only a small part in the recovery of the patient, his immunity being no doubt mainly the result of the streptococcal invasions after the primary focus of sepsis had been removed. Had the primary focus remained it is very unlikely that immunity would have been established.

The case is similar to other acute cases which have been under my observation, and illustrates the supreme importance of the most careful search for foci of sepsis—in the teeth, tonsils, antra, bowel, kidney, bladder, etc.—in cases of obscure septicaemia. It also illustrates the great importance of the removal, if possible, of the primary focus of sepsis, without which continued improvement is impossible.

## A FATAL INJURY OF THE VAGINA.

BY

R. BLAIR, M.B., Ch.B.,

RECENTLY R.M.O. IN DUNDEE ROYAL INFIRMARY.

IN 1899 F. Neugebauer, under the title "*Venus cruenta violans interdum occidens*," reported on over 150 cases of coital injury gathered from publications; but individual cases still have interest, which, in the case here reported, is heightened by the unusual sequel. Of Neugebauer's list twelve cases were younger than 16 years and six older than 40—namely, 45, 47, 48, 50, 58, 59. (R. C. B.)

A woman, aged 55, was admitted under Dr. R. C. Buist's care on January 1st. She had had three pregnancies—twice twins. The menopause occurred at 40. She had become a widow, but remarried four months previously, and a week before admission felt pain during coitus. Bleeding followed, and continued a few days. On vaginal examination or by douching. Three days later severe attacks began and had continued; she was admitted to hospital. She was thin, anorectic, and complained of headache. The temperature was 98, and the respiration 24; the skin was dry, the tongue dry and furred. No abnormal signs were found in the chest or abdomen. Pelvic examination showed: senile vagina, uterus small and anterior, os closed; appendages normal. Inspection with speculum showed a tear 3 in. long running down the right side from the fornix, tapering off toward the vaginal entrance and sealed with clot. The leucocyte count gave 10,000, with 77 per cent. polymorphs. The very dark urine contained bile pigment; Fouchet's test was definitely positive. Glucose-saline solution was given by rectum, at first continuously and then every four hours, and subcutaneous saline injections were given also. Fixation abscess was sought to be obtained on two occasions, but only induration resulted. Nuclein was given hypodermically and then by mouth. Blood culture was negative on two occasions.

On January 4th jaundice had deepened; the left parotid was swollen, but it subsided without suppuration. On January 5th the

leucocyte count was 13,000; blood urea-nitrogen 43 mg. in 100 c.cm. Each day one or more rigors occurred and mental confusion developed. The temperature ranged from 97° to 103°, and apart from a short rally on January 8th exhaustion increased till death on January 12th, nineteen days after the injury.

#### Necropsy.

A necropsy, conducted by Dr. F. M. Milne, showed a closed tear along the right wall of the vagina, with softening, but no pus in the paravaginal tissue; a dark thrombosed vein crossed the bark of the uterus to the left side, where it passed upwards to the brim of the pelvis; the left ilio-psoas muscle was purple-red in colour, in marked contrast to that on the right, and on section showed an appearance suggestive of gas formation to a slight degree. The liver was congested, but there was no abscess, no obstruction to flow of bile, and no gall stones; the spleen was enlarged; the lungs showed hypostatic congestion; kidneys were congested. The organs were otherwise normal.

Professor W. J. Tulloch examined the spleen and left psoas muscle bacteriologically, and reported in the muscle *B. welchii* and streptococci, both of which developed well in anaerobic culture; in the spleen were streptococci and Gram-negative bacilli; the latter were believed to be contaminants, but the former were "undoubtedly evidence of ante-mortem infection." With regard to the finding of *B. welchii* in the psoas muscle, it was thought that this might have been merely a post-mortem contamination, but "having regard to the condition of that area of muscle, it is quite possible that infection with that organism played a part in the pathology of the case."

My thanks are due to Dr. R. C. Buist for advice and for permission to publish the case, and to Dr. F. M. Milne and Professor W. J. Tulloch for their assistance.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### BULLET EMBEDDED IN TONGUE.

The following case, which we believe to be unique, seems worthy of record. We shall be glad to learn from readers whether similar cases have been recorded before.

A soldier came into the hospital one day complaining of a lump in his tongue, which on examination proved to be firm and hard. The tumour was oblong in shape, with its longitudinal diameter in line with the right lingual artery. A little nearer the tip of the dorsum there was a small fistula from which pus oozed when the tumour was palpated. He gave a history of having been wounded in the recent fighting between the Chilli and Fengtien forces, and a scar mark on his right upper lip bore testimony to our suspicion that the tumour may have been caused by a foreign body, which had become embedded and caused the sinus formation. He was operated upon, when a bullet was extracted. Had the latter penetrated a little further the lingual artery would have been injured.

London Mission Hospital, Tientsin.

P. T. LIANG.

#### CYSTIC HYGROMA OF CHEST.

The following case of cystic hygroma is reported on account of the unusual situation of the tumour and of its general interest.

A female baby, aged 6 weeks, was brought to the out-patient department of the Ingham Infirmary, South Shields, on March 23rd, with a large lump on the right side of the chest. The mother stated that it was present at birth, being then about as large as a hen's egg, and that it had got gradually bigger up to 5 weeks, and then commenced to increase rapidly in size. The tumour, the size of a Tangerine orange, was situated above and to the right of the right nipple. It was rounded, and not lobulated, and felt like a large cyst. There was no fluid thrill. It could be freely moved in the direction of the muscle fibres, but only slightly across them; it appeared, however, to be quite free in the sub-cutaneous tissue. The overlying skin was not adherent and was almost normal; there was no dimpling and only a suggestion of glazing. On the postero-lateral aspect of the right arm just above the elbow was a diffuse lobulated lipoma-like swelling, which the mother stated was also present at birth, but had not increased in size.

When I saw the child again, a few days later, the tumour had increased to the size of an ordinary orange. The overlying skin was now definitely glazed, and bluish in colour, but the tumour retained its former characteristics. It was thought to be some

type of degeneration cyst into which there had been haemorrhage, and removal was advised.

The child was admitted to the infirmary, and on March 27th Dr. Hamilton operated. The overlying skin was removed with the tumour, which was dissected out entire with some difficulty, as it was adherent to both the fascia and to the pectoralis major muscle, a small portion of which had to be removed. A small drain was introduced and the wound closed. Serum continued to escape for a day or two. The mass on the arm was not removed. The tumour consisted of a large central cyst with thick walls, and several small surrounding cysts. It was sent complete to the Clinical Research Association for examination. The following is the report:

"The section shows an extensive cystic hygroma, with evidence of continuous addition and haemorrhage. The walls are of granulation tissue, and the small cysts contain serum and lymph. Probably there was some abnormality of the blood vessels as well as of the lymphatic channels. There is no evidence of new growth."

The child was discharged on April 8th quite healed and in good condition.

I am indebted to Dr. Hamilton for permission to publish this case.

House-Surgeon, Ingham Infirmary,  
South Shields.

#### POST-MORTEM CAESAREAN SECTION: A LIVING CHILD.

On February 21st Mrs. S., a Khasi patient, was admitted at about 11 a.m. in an unconscious state. She was immediately placed upon an out-patient examining couch and I was summoned without delay. I found her in her first and final eclamptic fit. There was marked oedema of the legs, for which she had not sought any treatment as, according to her husband, a similar swelling had not caused her any trouble either prior to, or at the time of, her three previous confinements. Before any treatment could be undertaken she collapsed quite suddenly and died about three minutes after admission. Examination showed that she was at about term, and that the child was still alive. Death was so rapid and unexpected that two minutes or more were spent in making quite certain that it was actual and not apparent. It must have been about seven minutes after death before a very hasty Caesarean section was performed. An apparently lifeless full-time male child was delivered. Artificial respiration was undertaken with great energy and efficiency by the two European sisters attached to the hospital, and they were well assisted by the Indian nurses under training. Before the operation wound had been hastily approximated the child was crying. He had a number of slight fits during the first twenty-four hours, but has since done very well, and as I write—sixteen days later—is making excellent progress.

Khasi Hills Welsh Mission Hospital,  
Shillong, Assam. Ch.B.Liverp.

#### TREATMENT OF SYPHILIS THROUGHOUT PREGNANCY.

MANY syphilologists believe that once a woman has been infected with syphilis she should be treated throughout every subsequent pregnancy; but contrary views are held by some medical practitioners, who are supported in their opinion by the publication of cases in which one course of antisyphilitic treatment of an infected mother has been followed by a series of healthy children. The following case seems worth recording as it demonstrates the fact that even extensive past treatment will not necessarily prevent congenital infection.

A woman, aged 18, reported at a clinic in May, 1922, with lip chancre and papular syphilide: the Wassermann test of the blood was positive. She received, in addition to heavy dosage of mercury and iodides by the mouth, thirty-three intravenous injections of "914," totalling 17.5 grams, between May, 1922, and March, 1924. During that period the blood had been alternately negative and positive. It was considered to be a case of arsenic-fast spirochaetosis, likely to have benefited by the administration of bismuth. Menstruation ceased in February, 1924, and she consulted her medical attendant, who advised her to cease treatment during pregnancy. An apparently healthy child was born at term, but a month later snuffles and then anal condylomata appeared. The mother, on examination two months after confinement, was found to have large papular lesions on one labium majus from which *Syphiloma pallidum* was obtained.

Glasgow.

ROBERT FORGAN.

# Congress of Obstetrics and Gynaecology.

## DISCUSSION ON PUERPERAL SEPSIS.

As reported in the last issue, the fifth British Congress of Obstetrics and Gynaecology was held at the house of the Royal Society of Medicine from April 22nd to 24th, under the presidency of Dr. H. RUSSELL ANDREWS.

The first two sessions of the Congress were devoted to the subject of puerperal sepsis, and the three later sessions to miscellaneous papers. We published in the last issue (pp. 779, 783) the reports of the two committees—that of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, and that of the North of England Obstetrical and Gynaecological Society—on the prognosis and treatment of puerperal sepsis, also the communications by Sir Ewen J. Maclean on puerperal sepsis in Wales (p. 770), and by Dr. Gibbon FitzGibbon and Dr. J. W. Bigger on a clinical and pathological investigation of puerperal fever (p. 773). Other papers read at the same session were by Dr. L. P. Lockhart, on bacteriological examinations during pregnancy, and a statistical paper by Dr. T. H. C. Stevenson, of the General Register Office.

Dr. STEVENSON emphasized the distinctly seasonal character of the mortality from puerperal sepsis, and showed a series of illustrative graphs. He said that this mortality had a winter maximum in the fourth and first quarters of the year and a very definite and regular summer minimum in the third quarter. That rule applied almost without exception over the years 1911 to 1922. Not only was there a seasonal variation in the maternal mortality from cases returned as septic, but also a similar variation, rather less marked at both extremes, but still quite distinct, in cases of maternal mortality from other than septic causes—namely, phlegmasia alba dolens, and the miscellaneous complications of difficult labours. No doubt septic causes entered into these cases also, but he could only speak on the basis of the returns. Dr. Stevenson also dealt with maternal mortality in the period following demobilization (1919-20), and showed that the peak of the curve representing demobilization was repeated with remarkably complete coincidence, after an approximate interval of nine months, in the peak of the curve representing puerperal mortality. This particular excess related to a period of about five months' duration, and formed the only exception to the regular rhythm of seasonal change over the period of eleven years.

### GENERAL DISCUSSION.

In the afternoon a discussion took place on the more general aspects of the same subject. Dr. J. E. GEMMELL (Liverpool) was in the chair, and so much interest was taken in the debate that only by limiting speakers severely as to time was it possible to include within the scheduled two and a half hours all who desired to participate.

Dr. J. WHITRIDGE WILLIAMS (professor at Johns Hopkins University and obstetrician-in-chief at Johns Hopkins Hospital, Baltimore) opened the discussion. Referring to the reports of the two committees submitted to the Congress, he noted that the one included 247 cases with a mortality of 35.8 per cent., and the other 154 cases with a mortality of 76 per cent. This meant merely that more serious cases were included in the one than in the other, for it was inconceivable that results of treatment should differ so widely. Altogether there were 401 cases with a mortality of 48 per cent., which was good or bad according to circumstances—that is, the seriousness or otherwise of the cases. The reports showed that women who had been subjected to much manipulation were more likely to develop infection than those who had been left alone. It would be a mis-

fortune if the point of view which regarded puerperal infection as in great part contact infection were abandoned. It appeared that there was one type of case which would get well if left alone, and another type which would die no matter what one did. The reports agreed as to the heavy mortality—some 80 per cent.—among women who were subjected to intrauterine manipulation. For years in America he had been teaching that the worst thing that could be done was to interfere with the interior of the infected uterus. The reports differed markedly in the results following the use of antistreptococcal serum—the London committee brought forward 33 cases so treated, with a mortality of 18 per cent., the North of England committee 104 cases, and 72 per cent. mortality. This simply meant that a milder type of case was treated in London. All the information went to show that they were practically helpless in the treatment of severe cases of infection. When women had general streptococcal peritonitis they were likely to die whatever one did; with pyaemia, if left alone, two-thirds of them died, and if operated on probably half. On the other hand, cases which did not show these acute general conditions might recover if left alone, prognosis depending on the resistance of the patient and the virulence of the organisms. What was wanted was research, not purely obstetrical, but proceeding on general lines of bacterial investigation. The average case of infection, if left alone, took care of itself, but if the organism was virulent and the woman's resistance low death was the almost universal outcome no matter what one did. Drs. FitzGibbon and Bigger had reported that, roughly, streptococci were found in the vagina of the pregnant woman in two cases out of three—fortunately, they said, not of the haemolytic type. He believed, however, that any technique which employed the speculum for obtaining the vaginal secretion was not above suspicion. He had found that with the speculum contamination was carried up from the vagina. He thought it a misfortune to talk about endogenous infection as these authors did, except with the gonococcus and possibly certain saprophytic organisms. In 3,000 consecutive admissions to his clinic up to the end of 1924 there were 436 cases of raised temperature in which the possibility of intrauterine infection had to be considered—that is, a temperature of 100.4° or over on more than one occasion, the temperature being taken every four hours. In 226 of these cases cultures were taken, and *Streptococcus haemolyticus* was found in 32, the non-haemolytic variety in 34. In the whole series of cases there were three deaths. Two of the women who died had been brought in infected during or after labour; the other woman who died developed the infection in the clinic; she had the haemolytic streptococcus, and had not been examined vaginally. Therefore, out of nearly seventy women in whom the streptococcus was found the only woman for whose death the service could be said to be in any way responsible had not been subjected to any of the manipulations which ordinarily antedated puerperal infection. It was found that, of the entire number of women with bacteria in the uterus and presenting a febrile puerperium, 24 per cent. had had a spontaneous labour, had not had a torn perineum or any such catastrophe, and had not been examined vaginally or subjected to any manipulation. Of the group showing *S. haemolyticus* 31 per cent. offered no ordinary possibility of external infection. In some of these cases the woman had evidently conveyed infection to herself with her own hands, and in the majority of apparently causeless cases he thought there was, not an autogenous infection, but some form of external infection escaping recognition. The fact remained that out of 3,000 admissions there was only one death for which the hospital service could be said to be responsible, and even in that case the woman was infected, not by anything done in the service, but in some other way.

Professor W. BLAIR BELL (Liverpool) said that cases in which there was a sudden onset of septicæmia and no local resistance whatever would practically all die. In cases in which there was local resistance there was a chance, chiefly by surgery, of saving the patient's life. It must not be thought that a case with streptococic peritonitis was inevitably fatal. He had had one case, with no fixed lesion in the pelvis, but with general streptococic peritonitis, the streptococci being of the haemolytic variety; this case also had bronchopneumonia, and the haemolytic streptococcus was isolated from the sputum. By draining the fluid from the abdominal cavity and treating the patient in the open air she recovered. If, therefore, one did get an apparently hopeless case it was always worth while doing one's best in the attempt to save it. He proceeded to give some figures relating to cases in which the flora of the vagina had been examined. One point brought out was that coitus shortly before labour was a very likely means of conveying the streptococic infection. In 20 cases there had been a history of coitus within seven days of labour, and 4 of these were infected with the haemolytic streptococcus. A classification was also made of the cases according to clinical interference. It appeared that in 23 cases there was no interference (on the part of midwife or doctor) before admission, and among these the number of cases showing the haemolytic streptococcus was 1 and the non-haemolytic 4. In 24 cases in which there had been interference including digital examination before admission the number showing the haemolytic streptococcus was 3 and the non-haemolytic 6. In 15 cases there was interference before and after admission to hospital, and of these 3 had the haemolytic streptococcus and 3 the non-haemolytic. In 14 interference was only after admission and 2 cases showed the haemolytic and 2 the non-haemolytic streptococcus. The speaker also pointed out that puerperal sepsis was always worse during the first three months of the year.

Mr. VICTOR BONNEY (Middlesex Hospital) recalled a paper which he had read before a similar gathering some years ago in which he had advanced the conclusion that puerperal sepsis was principally autogenetic. He had pointed to the precautions which had been taken for many years against what might be called extrinsic sepsis, and to the fact that in spite of all such precautions the morbidity was very little altered. No one would deny the possibility of conveying germs from without into the uterus, but his contention had been, and still remained, that that only occurred in a small proportion of the cases. All the measures inculcated by the teachers had for their object the prevention of extrinsic sepsis, and yet the figures advanced that day seemed to him to prove very conclusively that sepsis was increasing. He noticed that in one of the reports the origin of the sepsis in very many of the cases was not stated. He wished the compilers of those statistics had been a little bolder, and had described these as cases of intrinsic sepsis. If the bulk of puerperal sepsis had been extrinsic then the measures which had been taken for many years, and recently with increasing rigour, would have occasioned a marked fall in the incidence, whereas any decline had been no greater than one might have expected if only a small proportion of the cases were of extrinsic origin. As a parallel instance, he mentioned that at the Chelsea Hospital for Women in 1900 the mortality rate for major abdominal operations was 5 to 6 per cent., and by 1906 it had fallen to 1.6 per cent., at about which figure it had remained. During the period 1900-06 gloves had been introduced, and had protected the patient against extrinsic sepsis, but were of no value against intrinsic sepsis, which continued in spite of these measures. It was making too much of the bacteriological evidence to believe that only haemolytic streptococci could give rise to sepsis. It had been argued that bowel organisms were innocent, but in fact they could be very harmful, and they were only kept in check on a very narrow line.

Professor HENRY BRIGGS (Liverpool) hoped that the committees which were reporting on the subject would allow the term "puerperal fever" to remain, because there was a great deal to be said for it. The reports

spoke of a pyrexial period without stating exactly what was meant by that term, and what temperature constituted its onset.

Professor BECKWITH WHITEHOUSE (Birmingham) said that puerperal sepsis depended largely on two factors: the amount of damage done to the tissues, and the amount of hæmorrhage which had occurred beforehand. He had taken 500 consecutive cases and had caused his students to follow them out. Out of 50 of these cases examined bacteriologically, 5 showed hæmolytic streptococci; these 5 went through a perfectly normal labour and puerperium. This group of cases included a certain number of forceps deliveries. Low forceps was employed 17 times and high forceps 5 times, and among these last 5 cases were 3 cases of morbidity. He thought that in the interest of the nation every woman, at least during the eighth month of pregnancy, should have the advantage, not only of the attention of a midwife, but of a doctor. A midwife could not be expected always to recognize a minor case of contracted pelvis. If all cases were seen by the medical profession it would be possible to group them according to expectation, as to whether they could be left with the midwife or whether minor or major difficulties were likely to be encountered. He agreed with Professor Blair Bell as to the likelihood of infection being conveyed by recent coitus.

Dr. F. J. McCANN thought that "puerperal general infection" would be a better term than "puerperal sepsis." It was well to retain the word "infection" because it brought home to all concerned the fact that puerperal infection was comparable with wound infection in general surgery. The hope in treatment was ante-natal care, and the question was closely associated with housing. Much could be done by instruction in cleanliness, and also by the provision of cheap obstetric outfits for the poor. If the mortality only were considered a wrong conception of the extent of this disease would be obtained. One had to consider the countless number of women who suffered from the effects of puerperal sepsis—chronic metritis, cervical catarrh, cicatricial scars, badly healed perineal tears, and so on. These women were to be numbered by the thousand. Provision ought to be made for the admission of sufferers to general hospitals. It was a blot on the scientific intelligence of the profession that to-day these women should be admitted to fever hospitals; they should go into ordinary hospitals, where their condition could be studied, and where they could have the advantage of all the equipment commanded by the modern hospital. He believed that a bad infective case should never be given up. One very successful method of treatment was starvation. In a case of peritonitis if one went on feeding the patient intense toxæmia was likely to develop from which the patient would ultimately die. But he could recall at least one case in which, after starvation, the pus became localized and he was able to drain. Another line of treatment was the old-fashioned "cold pack." He wondered how many members of the Congress were accustomed to employ it; it was one of the best things in what was known as the "typhoid state," and he had seen patients rescued from the grave by the "cold pack."

Dr. B. DAWSON, who represented the Australian Government at the Congress, said that Australia at present had a higher mortality than Great Britain in cases arising from parturition. The figures for Australia in 1922 were 4.7 per 1,000, for England 3.81. The death rate from septic conditions alone was practically the same in both countries, and there was the same curious difference between rural and urban areas. In urban areas, whilst the death rate from septic causes was high, the death rate from other causes was low, and the reverse was true of the rural districts. Although women in the urban districts had the benefit of greater skill and attention, and thereby some catastrophes of labour were avoided, the increased amount of interference which they received might perhaps account for the higher septic rate. There was nothing in Australia corresponding to the Central Midwives Board, and

the country was in a similar condition to that obtaining in England twenty years ago, when a large number of entirely unsuitable and dangerous women were practising as monthly nurses. Women in the rural districts of Australia lived frequently under very bad housing conditions and had to do exhausting work; on the other hand, they had abundant sunshine, fresh air, and good food. He pleaded for an imperial, possibly an international, system of recording cases, so that the amount of dependable statistical material would be increased; also that bacterial technique should be standardized as far as possible, and that in certain well defined clinical conditions treatment also might be more or less uniform.

Dr. REMINGTON HOBBS (medical superintendent, Kensington Infirmary) said that exploration of the cavity was certainly contraindicated in a uterus in a state of sepsis. The only cases in which such exploration should be done were those of severe haemorrhage. If success in treatment was to be attained the uterine tissues must drain efficiently. There was often a mechanical block in the cervical canal. With regard to treatment, he thought that more reliance might be placed on glycerin, which produced an osmosis of the tissues and drained the cavity as well as the cervical canal. The reason for some failures was that doctors did not realize that the uteri required many treatments—many glycerin treatments, for example. When inflammation had spread to the Fallopian tubes attention should be directed first to the uterus, which was painful and tender, and if the uterus were drained there would not be a necessity for removing so many of the Fallopian tubes. He felt that but for some failure in the technique of treatment there would be a larger number of permanent cures.

Colonel L. W. HARRISON (Special Medical Officer for Venereal Diseases, Ministry of Health) referred to the statistics on puerperal mortality and demobilization which Dr. Stevenson had brought before the Congress. He thought that they might be explained by a considerable increase in the rate of gonococcal infection of wives by men on demobilization. On this hypothesis the gonococcal infections which took place at the time of conception were succeeded by infections with mixtures of organisms, including that, or those, responsible for puerperal fever. Mixed infections were, of course, a very common sequel of gonorrhoea in women as in men, and he was sure that in many cases of so-called chronic gonorrhoea in women the endocervicitis was due, not to the gonococcus, which had long since been thrown out, but to streptococci, staphylococci, diphtheroids, and other organisms, which would not have gained a footing in the mucosa if the ground had not been prepared for them by the gonococcus. Very large numbers of men must have left the army on demobilization suffering from gonorrhoea. The incidence of venereal diseases among the troops immediately after the armistice was, he believed, four or five times what it had been during the war. He thought it would be interesting to see if the period of most active demobilization was followed by a marked rise in the incidence of ophthalmia neonatorum, and this had proved to be the case. The notified cases of ophthalmia neonatorum per 100,000 births since 1915 had been as follows:

1915 ..	835	1918 ..	986	1921 ..	979
1916 ..	969	1919 ..	1,249	1922 ..	911
1917 ..	1,004	1920 ..	1,076	1923 ..	870

The peak of notified ophthalmia preceded that of puerperal mortality by about three months, and it might be, as Dr. Stevenson had suggested to him, that gonococcal infection contracted some months after conception was more likely to be followed by ophthalmia neonatorum than was gonococcal infection at the time of conception. The rates of notified puerperal fever and ophthalmia neonatorum for the county of London from 1915 to 1923 showed a steady decline in ophthalmia since the first quarter of 1921, but the rate of notified puerperal fever was as high at the end of 1923 as at the end of 1919. If there was a connexion between gonococcal infection and puerperal fever he would suggest that when a woman was infected with gonorrhoea the risk of ophthalmia neonatorum might be chiefly at the

next birth, but the risk of puerperal fever persisted, since the mixed infection was not so quickly thrown off as the gonococcal. All this did not prove that gonococcal infection prepared the ground for the germs of puerperal fever, but he thought that the figures were suggestive, and that more ante-partum attention to infections of the vagina and cervix would considerably reduce the incidence of puerperal fever.

Dr. F. W. GORDON (New Zealand) said that his country had the lowest infantile mortality in the world, but one of the highest maternal mortalities. He wondered, however, whether the statistics of maternal mortality published in the British and Continental journals were a reliable guide to the incidence of puerperal sepsis. In New Zealand it was now necessary to notify the puerperal morbidity. In every public and private hospital, if a patient had a temperature of over 100° F. for more than two days the case had to be notified to a Government inspector.

Dr. H. J. PHILLIPS brought forward some figures from the Monsall Fever Hospital, Manchester, where a block was set aside for puerperal sepsis cases. The figures related to the whole of the cases treated in that block from January, 1924, to March, 1925. During the first eight months of that period he continued treatment on ordinary lines, from non-interference up to ennetting, and of the 55 cases so treated 13 died, and the average stay in hospital of the recovered cases was thirty-nine days. Afterwards he treated the cases by lymph drainage (glycerin in the uterus) combined with immunotransfusion in a few septicæmic cases, and the results had exceeded his expectations: Of the 45 cases so treated only 6 had died, and the average stay in hospital of the recovered cases was 25.9 days. Of the 42 recovered cases which were treated on ordinary lines complications occurred in 23: general peritonitis 1, pelvic peritonitis 2, lobar pneumonia 2, salpingitis 3, pelvic cellulitis 1, pelvic abscess 2, parametritis 3, phlegmasia dolens 2, single abscess 5, multiple abscesses 2. Of the 39 cases treated by lymph drainage complications occurred in 3: pelvic abscess 1, parametritis 1, single abscess 1. The number of major operations performed in the first set of cases was 5, and in the second set 1.

Dr. JAMES HENDRY (Glasgow) gave an account of certain groups of cases—a rough total of 63 out of 745 confinements in the institution with which he was connected—which showed a rise of temperature, and analysed the causes so far as these were ascertainable. A certain number were due to general diseases or ante-natal infective conditions—such as tonsillitis, for instance. On 14 cases, dealt with domestically outside, the forceps had been used, and the patients afterwards admitted to the institution; of this number 5 cases showed pyrexia, four of them of the most severe type. Of the severe cases clinically there were only 6 in the whole series; of these, 4 were fatal, 3 of the 4 being cases of "failed forceps" in which there had been extensive bruising and laceration of the tissues.

Dr. C. E. DOUGLAS (Cupar, Fife) stated the case from the general practitioner's point of view with regard to the etiology. He based his remarks on the statement often made at consultations that easy cases often developed sepsis, and that difficult labours seldom went wrong. One of the reports stated, "Our figures do not at all bear out the latter part of this view, but show that in 25 per cent. of cases there is no obvious etiological factor present." He welcomed the latter statement, and thought that much would be made of it; the former statement was also true in a sense, but the figures were not available—that is to say, it was not known from what number of normal labours these others were extracted. Dr. Douglas proceeded to give the figures for his own practice, dating back to 1880. During that period he had had 2,200 maternity cases. He had done 393 forceps operations, and had had only one septic death, some thirty years ago. He had also done 164 other operations—versions, removal of placenta, etc.—without a death, making in all 557 operations with one death. On the other hand, in the remaining 1,663 cases he had had 5 septic

deaths, or 1 in 333, showing that the risk in normal cases was at least as great as in operations carefully conducted. In his last 1,670 cases taken consecutively he had had 2 septic deaths (1.7 per 1,000), and in both cases there had been the minimum of manipulation. Taking the statistics presented to the Congress, did not even the best of them point to an irreducible minimum of something under 2 per 1,000? Why was this? Why was such extreme care necessary? Was it not that some factor was present which had not received sufficient attention? He thought the forgotten factor was the woman herself. Might it not be that the parous woman, *ipso facto*, was apt to die? With heart disease, tuberculosis, and other conditions, a woman might go on for years, but if she became pregnant, while Nature sustained her to fulfil her duty to the race, she died after labour. There seemed therefore, *a priori*, some reason to suspect that the parous woman differed from her non-parous sister. The clinicians apparently had no more to say, but the physiologists and the biochemists had thrown some light on the subject. Percy Herring had recently shown that in albino rats there were very definite changes in pregnancy. The liver was increased 27.5 per cent. in size, the adrenals 10 per cent., while the thyroid was decreased 10 per cent. and the pituitary 24 per cent. The biochemist showed that the nitrogen exchange was affected to an important extent, much nitrogen being stored up in the later months, far more than could be needed for foetal and placental tissues, while the renal threshold for sugar was lowered, and a condition of hydraemia existed, a minor degree of the dropsy which was sometimes met with. How, in the face of these facts, could the view be maintained that a pregnant woman was just a healthy person who was going to have a baby? The inference was obvious. She must be studied from quite a different standpoint. More must be learnt about the woman herself, not what micro-organisms were infecting her. Her opsonic index, her power of active immunity against sepsis, and so forth, should be studied. From the clinical point of view the extremists on both sides should be brought to task, both those who roughly handled her and those who, fearful of doing harm, would leave her till she was exhausted before giving her help. The parous woman was a delicate creature, defenceless against infection, and should be dealt with—always, however, with the utmost gentleness.

Lady BARRETT (Royal Free Hospital) described the results of a series of investigations of cases of morbidity. These investigations, she said, had been undertaken from the point of view of discovering the best way to end the sepsis in each case. It was found that old gonorrhoeal cases might be followed by streptococcal infections in the vagina. There were two separate outbreaks of infection occurring in this series which had, apparently, quite different causes. In one of these the infection appeared to be due to the accoucheur, who was suffering from oral sepsis, and who was responsible for four cases of severe streptococcal infection. In another outbreak of infection it was difficult to find anything in common so far as the handling of the cases was concerned, because they had been delivered and nursed by different people, but on going into the history it was found that every one of them had been placed at one time in a particular ward. No further admissions to that ward were allowed until it had been fumigated and disinfected, and no other case of infection arose. It was also evident that in certain cases a sloughing vagina might be the starting-point of sepsis which appeared to ascend into the uterus at a somewhat late date. One was more impressed, said Lady Barrett, by the women who were not infected than by the women who were. The women not infected greatly outnumbered those who had any sign of morbidity whatever, and one was driven to feel that, however useful the investigation of sepsis itself might be, the kind of research which was urgently needed was a research into the causes of resistance of women during pregnancy and the puerperium. Possibly research into the bactericidal powers of the blood in women during pregnancy and again in the early days after delivery might lead to some method of reinforcing the resistance, and hence perhaps offer a means of diminishing the incidence of puerperal infection.

Mr. ALECK W. BOURNE (St. Mary's Hospital) said that in the London report presented to the Congress the cases might be divided, from the point of view of treatment and prevention, into two groups: one group, consisting of 25 per cent. of the cases, had no apparent etiological factor, and here the problem of prevention required more extended bacteriological and serological work; the other 75 per cent. of cases directly concerned obstetricians from the point of view of prevention, and what they had to do did not differ at all from what the general practitioner was called upon to do. He emphasized the enormous importance of ante-natal examination and treatment and the minimum of ante-natal interference. Much of the teaching of students of the present day was devoted to points which were abstruse and of small practical value. When students were sent out more thoroughly equipped for the exercise of ante-natal care a great step would have been taken towards the stamping out of puerperal fever. A large number of women, especially in the rural districts, had no ante-natal care. He was convinced that in course of years, by attention to this and other points, puerperal sepsis would be brought down to an irreducible minimum. One speaker (Dr. McCann) had mentioned the housing factor, but, according to the Registrar-General's report, Shoreditch, where the housing conditions were in many cases squalid, had the lowest maternal mortality of any metropolitan borough, while in Hampstead, where the housing was good, the maternal mortality was relatively high.

Dr. T. WATTS EDEN (Consulting Obstetric Physician, Charing Cross Hospital) said that the systematic study of puerperal cases had hardly begun. The question of whether the bulk of sepsis was extrinsic or intrinsic had not even been settled. It was not known what was the real significance of streptococci in the vagina. Not as much was known about the pathological anatomy of puerperal sepsis as was desired. Many gynaecologists learnt what little they knew about puerperal sepsis from cases seen in consultation, and they did not see these cases as a rule until they were in their last stages. It seemed to him impossible to undertake anything approaching a systematic study of puerperal sepsis unless hospital facilities were available for studying the condition from beginning to end. The cases must be studied in an institution where it was possible for bacteriological work and modern methods of investigation to be carried out. Government assistance was necessary to this end; hospitals could do little or nothing unaided. He suggested that the Congress should send to the Ministry of Health an expression of its opinion on the necessity of such provision of hospital accommodation.

It was agreed that such a resolution should be drafted, and at a later stage of the Congress the following resolution was submitted from the chair and carried unanimously:

In the opinion of the British Congress of Obstetrics and Gynaecology the most urgent requirement in connexion with the problem of puerperal sepsis is the provision of adequate accommodation for the reception and treatment of these cases in hospitals, supervised wherever possible by obstetric surgeons.

Dr. RUSSELL ANDREWS (President of the Congress) replied to one or two critics of the report of the London committee. The compilers of that report could not insert matters which they had not got in the returns submitted to them. Mr. Victor Bounce had said that a bolder course ought to have been taken, and that in the cases in which the origin of the sepsis was not stated it ought to have been put down as intrinsic. But the committee had no right to do that; it could merely state that there was no obvious cause of infection. Professor Briggs, again, appeared to think that the committee had not behaved quite as it should with regard to pyrexia, but the committee was bound to go by its records. Several speakers had said—and he fully agreed—that in ante-natal supervision lay the chief hope of prevention. He had been interested in Professor Whitridge Williams's view about treatment in severe cases. It was a gloomy view, but it recalled to him what the late Dr. Herbert Williamson had said three or four years ago. Dr. Williamson had asked him what he thought was the treatment in such cases, and he had replied, "To

my mind, nursing, and look out for pus," to which Dr. Williamson replied, "Well, it is a gloomy view, but I absolutely agree with you." It appeared that many of the treatments suggested were not necessarily of any great avail. He added that as one responsible for the arrangement of the discussion his principal regret was that the time limit should have prevented Dr. C. E. Douglas from developing fully his admirable survey of the subject as a general practitioner.

The CHAIRMAN (Dr. Gemmell), in closing the discussion, said that he thought obstetricians ought to be extremely careful about the views they advanced on the question of autogenous or non-autogenous infection. The lay mind, especially the legal mind, was always on the look-out for some reason for saying, "There you are; it is your fault." To say that puerperal sepsis was autogenous was to a certain extent dangerous, and to proclaim the opposite view might be also dangerous, so that until the question was further elucidated it was well to exercise some reserve in the expression of opinion.

The three remaining sessions of the Congress were devoted to communications and discussion thereon.

#### *Prolapsus Uteri.*

Professor W. W. CHAPMAN (Montreal) read a paper on prolapsus uteri, which he described as a sacro-pubic hernia through the fibrous diaphragm of the true pelvic floor. In common with all hernias, it had a canal of descent, a sac, a sac-content, and sac-coverings or wall. It was the inclusion of the important organs—namely, the uterus, the bladder, and the anterior wall of the rectum—in this sac-covering or wall that had formerly misdirected the attention. This sacro-pubic hernia was a sliding hernia, a *hernie par glissement*. The essential part of the pelvic floor was the fibro-fascial hammock, while above was the accessory support of the peritoneal ligaments, and below the accessory support of the sphincteric layer. The speaker illustrated the support of the uterus by the analogy of a girl seated in a swing, the seat the fibro-fascial hammock. She was steadied in this seat by her arms grasping the ropes above—these arms were the peritoneal folds or ligaments. There was a foot-rest below which, in the analogy, was the sphincteric muscular layer of the pelvic outlet. He then showed in lantern slides the operation which was employed in Montreal. It consisted in the exposure of the fascial cleft, the replacement of the viscera, and the radical cure of the hernia. It was a simple operation, he believed it was anatomically sound, and during the past ten years it had given satisfactory results. He made no claim to special originality. What he brought forward was rather a surgical synthesis, gathered here a little and there a little, and combined into a definite procedure.

#### *Backward Displacement.*

Dr. BETHEL SOLOMONS (Dublin) communicated the results of a questionnaire sent to patients on whom he had performed the subperitoneal Gilliam operation during the last six years. He referred to the divergent views held with regard to the treatment of backward displacement, and to the many symptoms dependent on this displacement. His object in making an inquiry as to the after-results of this operation was to find out if these symptoms had been relieved, to obtain knowledge as to pregnancy after the operation, and especially as to whether there had been difficulty in labour; also to find if the uterus remained in the suspended position, and if there were any untoward symptoms following the operation. Letters were sent to 235 patients upon whom an operation had been done more than a year previously, and answers were received from 176. Of this number, 107 had complained, previous to operation, of some form of backache, and 101 of these now reported relief of this symptom. In the series of unmarried women there were 6 whose cervixes had been dilated without relief of symptoms, and these had been cured since the Gilliam operation was done. Of the 176 women who replied, 67 had had full-term children since the operation without trouble in labour; 3 had had both children and miscarriages, and 3 had had miscarriages

alone. In no case had displacement of the uterus occurred, and in one case only was slight discomfort reported, probably due to a pull on the ligament. He insisted strongly on the use of silk as suture material; if catgut were used there would be a recurrence of the displacement.

In a brief discussion the advisability of performing an abdominal operation as a matter of course for retroversion came in for criticism. Professor B. P. WATSON referred to the difficulty of diagnosing the real cause of the backache or other symptoms in such cases. One of the commonest causes was cervical laceration, with catarrh, in parous women. He believed that in most cases of retroversion which gave rise to symptoms, the backache was not due so much to the retroversion as to the associated prolapse, and a great many of these cases could be relieved by an operation such as Dr. Solomons had described. Mr. LEYLAND ROBINSON said that three or four years ago Dr. Gemmell and he published the results of 220 cases in which the operation of ventrofixation had been performed—an operation which, he gathered, Dr. Solomons regarded with disfavour. Of these patients 179 described themselves as cured, and although 41 others complained of symptoms a closer analysis showed that only six or seven were possible failures; moreover, 68 of the patients had had 108 children without the slightest obstetric difficulty. Professor C. G. LOWRY mentioned the frequency of dyspareunia among women who had chronic backward displacement. Dr. SOLOMONS, in reply, said that he did not perform an operation in every case of backward displacement, and he agreed that it was wrong to operate in the absence of clear indications. In ceasing to perform the ventral suspension operation he had followed the teaching of Howard Kelly; this operation could be done successfully by individual operators, but students watching its performance never seemed to get the correct technique, and disasters followed.

#### *Premature Separation of Placenta.*

Professor J. WHITRIDGE WILLIAMS (Baltimore) showed lantern slides of a specimen of placenta prematurely separated and gave an account of the case. The patient was aged 33, pregnant for the third time. She was seen in the out-patient department eighteen days before the accident, when she was in normal condition. On admission to the hospital later she had a pulse of 140, a temperature of 101°, low blood pressure, and haemoglobin content of 32. A diagnosis of premature separation of the placenta, with concealed haemorrhage, was made. Hysterectomy was performed and the unopened uterus removed, but the woman died of shock, with all the appearances of intra-uterine haemorrhage. The autopsy showed that haemorrhage could hardly be the cause, and he was inclined to believe that as a factor in producing shock the dissociation of the muscle fibres of the uterus played a very important part. He added that out of 9,000 admissions to his hospital there had been 57 cases of premature separation of the placenta and 64 cases of placenta praevia. Premature separation of the placenta was, therefore, a fairly common condition. His analysis related only to 40 of these cases, among which there had been 3 maternal and 29 foetal deaths. In these 40 cases in no instance was there an unusually short cord, and there was no sign of torsion; a microscopical examination was made in every instance, and there was no sign of decidual endometritis. Syphilis played no part in this condition; a Wassermann test was carried out on 37 of the women, and was negative in all but 3 cases. It was said that albuminuria played a part in causation, but only 15 of these women showed any signs of albuminuria before or after the accident. Of the three women who died, two came to autopsy, and in neither case was there any sign of toxæmia; the liver and kidneys were normal.

Professor P. B. WATSON thought that the separation of the placenta was not the initial process, but that haemorrhage into the wall came first, and the separation was the mechanical result. The lesion was really of the nature of an infarction. Some years ago he had a case of spontaneous rupture of the uterus, and there the histological picture of the uterine wall was exactly the same as that

found in cases of accidental separation of the placenta, and it was a question whether the two conditions were not analogous. If the infarction of the uterine wall occurred in sufficient degree at an area other than the placental site rupture might take place, and if at the placental site there might be premature separation. Dr. R. H. PARMORE suggested that just as coitus in late pregnancy might be the cause of puerperal sepsis, so it might be the cause of premature separation.

#### *Endometrioma.*

Professor A. DONALD (Manchester) brought forward a clinical study of endometrioma. He surveyed 108 cases, distributed among six gynaecologists, in all of which cases operation had taken place during the last four years. Of these patients, 16 were under 30 years of age, 46 were aged between 30 and 40, and 46 were over 40. Of the 93 who were married women, 37 were nulliparæ, 22 had one child, and the others more than one. The date of the termination of the last pregnancy in 35 cases was over seven years previously. By far the most important symptom of the condition was dysmenorrhœa, which was present in 70 per cent. of the cases; menorrhagia was present in 57 per cent., leucorrhœa in 38 per cent., and backache in 28 per cent. There was dyspareunia in 32 per cent. The most important physical sign was the thickening of the appendages, which was present in 74 per cent. The conditions found at operation included fibroids in 26 per cent. of the cases, tarry cysts in 77 per cent., adenomyoma in the recto-vaginal space in 63 per cent., and adherent rectum in 76 per cent. The operation which was done in 50 cases was partial hysterectomy with removal of both appendages, and in 38 cases supravaginal hysterectomy, also with removal of both appendages. The remaining cases were treated by dissection of growth from abdomen or per vaginam, removal of one or both ovaries, or myomectomy. Of the 108 cases only one died.

Dr. K. V. BAILEY followed with an epidiascope demonstration of the pathology of the condition. He concluded that in these cases there was a primary disposition on the surface of the pelvic organs of endometrial epithelium, the result of regurgitant menstruation from the uterine cavity. In his belief this phenomenon of regurgitant menstruation was of much greater frequency than was at present supposed. It was one of the causes of dysmenorrhœa and a possible causal factor in ectopic pregnancy. The secretion prepared the surface of the pelvic organs for invasion, but the various tissues reacted in very different ways to these elements.

#### *Treatment of Cervical Carcinoma by Radium.*

Dr. MALCOLM DONALDSON (St. Bartholomew's) described the treatment of inoperable carcinoma of the cervix by radium. He distributed to members of the Congress an analysis of every one of 85 cases treated from May, 1921, to February, 1925. Of this number, 74 were hopelessly inoperable, 5 were on the borderline, and 6 were operable but for various reasons were not operated upon. Of these 85 cases, 31 were now living and 54 had died. Taking only the 58 inoperable cases which had been treated for a year or longer, 8 were living, one of whom had lived for forty-seven, one for forty-one, and one for thirty-nine months. In the vast majority of cases—85 per cent.—haemorrhage disappeared entirely within a few weeks of the radium applications, and if it returned at all did so a short time before death. In 63 per cent. of the cases ulceration cleared up entirely, either temporarily or permanently. Of those cases in which cauliflower-like growth was present, in 70 per cent. it disappeared entirely. The general condition of the patients in the majority of cases was very much improved, and in numerous instances they were able to do their work in comfort for many months, and the duration of life was prolonged in a certain number.

Dr. GILBERT I. STRACHAN (Cardiff) also described the treatment by radium of 40 cases of carcinoma of the cervix. The dose usually employed in these cases was 150 mg., inserted for twenty-four hours. The haemorrhage was the symptom most completely controlled. Considerable im-

provement, amounting to clinical cure, had been obtained in 17 cases. He believed that for inoperable carcinoma of the cervix radium presented the most potent therapeutic agent available.

[The papers by Dr. Donaldson and Dr. Strachan will appear in an early issue of the JOURNAL.]

Dr. T. WATTS EDEN said that these two communications showed that the use of radium at any rate relieved the sufferings of these women, and perhaps prolonged their lives. The action of radium was extremely localized, and Dr. Donaldson deserved congratulation on the plucky way in which he had tried to get his radium into actual contact with the glands. There was no doubt that with radium it was possible to destroy almost completely the local growth, but no effect might be produced on the distant parts or upon the involved glands. It almost looked as if surgery had said its last word about cancer of the cervix. The extended operation had been carried to a point from which, he imagined, no further advance was possible. It would be necessary to look to radium alone in cases in which an operation could not be done. At Charing Cross Hospital he had used radium in a few cases of cancer of the cervix on which it was intended to operate. He used it in the old-fashioned way—now generally abandoned in favour of a better envelopment by tubes in different positions—of simply putting the tube in the cervical canal, but the local improvement that took place struck him as very unusual. Not only did the ulcerated condition clear up, but the mobility of the uterus was very greatly increased. He believed that the future treatment of cancer of the cervix lay in the combination of radiology and operation. It might be found that if cases were irradiated before operation more satisfactory results would follow from the surgical procedure. Possibly deep x-ray therapy might prove more efficient than radium in dealing with the deep-lying glands.

Professor CARLTON OLDFIELD said that after some experience he was not inclined to try again the treatment of an operable case by x rays, but he thought it worth while to treat by this method cases not operable. One or two speakers mentioned that pain followed radium application, but Dr. DONALDSON, in his reply, said that this was only a fleeting manifestation.

#### *Albuminurias of Pregnancy.*

It was unfortunate that the only two papers read by women at the Congress had to be crowded into the last half-hour of the second day's session, with no opportunity for adequate presentation or discussion. Dr. AGNES BENNETT (Wellington, N.Z.) spoke on the albuminurias of pregnancy as studied in the State maternity hospitals of New Zealand. She said that in 1923 the New Zealand Branch of the British Medical Association arranged with the health authorities that eclampsia should be notifiable; like infectious diseases. She had had access to forty-nine of the notification forms returned by forty-one different practitioners, and the survey showed the extraordinary variety of the treatment followed, the small amount of experience of the condition on the part of the individual practitioner, and the high mortality of Caesarean section. In these State maternity hospitals eclampsia and albuminuria were the causes of the largest number of deaths, both maternal and foetal. In 1920-24 24 per cent. of all puerperal deaths registered were due to puerperal albuminuria and convulsions. Dr. Bennett described the ante-natal treatment, whereby some albuminuric cases had been resolved by careful dieting and had come to natural labours. One of the principal things which had come before her in this work had been what she termed "invisible oedema," and she found on a recent visit to the Mayo Clinic that there also they were getting out most interesting pre-natal charts in which, in practically every case, albuminuria had been predicted by an undue rise in the weight chart.

#### *Toxaemias.*

Professor A. LOUISE McILROY, with Dr. E. PILLMAN WILLIAMS, discussed the toxæmias of pregnancy from their clinical and chemical aspects. Professor McIlroy, under the compulsion of the Chairman's time-signal, had to condense

her voluminous paper so drastically that it is doubtful whether those who listened to the shorn presentation appreciated the great amount of work it involved. She said that of the principal disposing causes of toxæmia a chronic intestinal condition was found in the majority of cases. Dysmenorrhœa had been noticed in the history of a number of these cases. In a few cases disturbance of vision, even to blindness, had been found. She discussed first toxæmias without albuminuria (vomiting, headaches, etc.), and then the albuminurias, including nephritis, cystitis, and pyelitis, and others, after which she spoke of the clinical significance of the symptoms and signs of toxæmia, the chemical significance of the examination of the blood and urine, and, finally, the results of toxæmia upon the ovum and foetus. One special point was the question of the induction of abortion as a result of the chemical findings. Abortion was a confession of failure in treatment. The indications for the induction of abortion were a persistent high blood pressure (180-200 Hg), blood urea exceeding 40 mg., bad ratio in urea concentration, also increase of albumin in quantity and diminution of urine. Out of 172 cases covered by her survey, in only three had abortion to be resorted to—one for novarsenobenzol poisoning, one for pyelitis (the other kidney having been removed for calculus), and one for placenta prævia.

#### *Menstrual Changes.*

Dr. WILFRED SHAW read a paper on the relationship between ovulation, corpus luteum formation, and menstruation. He described some work in which the endometrium and ovaries of women who were menstruating regularly were examined. The date of occurrence of the earliest premenstrual changes was found. The ovaries were examined for early corpora lutea, and the date when ovulation occurred was deduced from this investigation. The structure of the corpus luteum was examined, and the changes taking place during menstruation and pregnancy were followed. It was shown that a relationship existed between the maturity of the corpus luteum and the development of the premenstrual changes. Degeneration of the corpus luteum was found to occur during menstruation. Ovulation took place at or about fourteen days from the menstruation and the corpus luteum was formed. If pregnancy occurred the corpus luteum persisted, the period was missed, and the premenstrual endometrium became the decidua. If pregnancy did not occur the corpus luteum degenerated, and the degeneration of the premenstrual endometrium followed, to be manifested by the phenomenon of menstruation.

#### *Implantation of the Ovum.*

The final event of the Congress was a lecture by Professor J. H. TEACHER (Glasgow) on the implantation of the human ovum. He gave a masterly description, illustrated by the epidiascope, of the comparative embryology, and drew particular attention to the nature of the closing mechanism of the decidua capsularis, the relations between the maternal blood vessels and the ovum in the earliest known stages, and certain theoretical considerations relating to the nutrition of the ovum prior to implantation and to the process of implantation. Professor Teacher remarked that the human ovum showed an immense amount of individuality. It differed from any type known to comparative study, and in fact the process of embedding and union with the maternal organism varied greatly even in members of the same group. There were an infinite variety of ways in which union between the ovum and the mother was obtained. It was shown many years ago that fertilization and implantation did not correspond to any part of the cycle in particular, but might occur at various points. There was fair agreement now that insemination in the higher mammals was generally followed within a very short time—an hour or two—by fertilization. Probably the rupture of the follicle only coincided with insemination, and the fertilization occurred very rapidly after that. Another very interesting point was that a good many of the ova must be embedded after the end of the interval. It was evident that it was not the implantation of the ovum which stopped menstruation. His own theory was that what stopped menstruation was fertilization. From certain observations which he

had been fortunate enough to have opportunity to carry out it appeared that implantation must have occurred from the third to the sixth day after the due date of the menstrual breaking down, and he thought it followed necessarily that fertilization must be the cause of the arrest of the cycle. It seemed unthinkable that so momentous an occurrence as fertilization should not in some way be communicated to the body as a whole. He had no doubt that it influenced the development of the endometrium; it must also influence the development of the corpus luteum. It seemed probable that when the spermatozoa entered the ovum there was a tremendous activity on the part of the ovum, which threw out some stimulating secretion upon being fertilized.

Visitors attending the Congress were received at various maternity hospitals and other institutions in London, and another feature of the Congress was a pathological exhibit arranged at the house of the Royal Society of Medicine.

## Reports of Societies.

### IMMUNIZATION AGAINST SCARLET FEVER.

At a meeting of the Section of Epidemiology of the Royal Society of Medicine on April 23rd, with Dr. JOHN C. McVAIL in the chair, the subject of immunization against scarlet fever was brought forward by Dr. MONCKTON COPEMAN of the Ministry of Health, who recapitulated the recent work on this subject by Drs. George and Gladys Dick, which was discussed in a leading article in the *JOURNAL* of last week (p. 792).

Dr. Copeman said that in this country scarlet fever, fortunately, was nowadays a much less serious disease, *qua* mortality, than was the case in his own earlier experience, but in America it still ranked high as a fatal malady among children under 9 years of age. During a recent official visit to New York he was afforded an opportunity of seeing the work on immunization at the Willard-Parker Hospital under the direction of Dr. Zingher, assistant director of the Public Health Department, based on the test given by Drs. Dick of Chicago. The test exhibited many analogies to the Schick test in diphtheria. In a series of papers the Dicks had set out the results of their study of the bacteriology of scarlet fever, showing, apparently, that a hæmolytic streptococcus, long recognized in the naso-pharyngeal passages of patients with scarlet fever, was probably the agent of the disease. Experimental work on animals had not proved successful, and the tests had to be made on human volunteers. Incidentally it was remarkable that in America relays of such volunteers were forthcoming without any difficulty. A number of volunteers were obtained who had lived under country conditions all their lives and had had no history of scarlet fever; the process of testing them was described in detail in the last issue. They were inoculated with a culture after it had passed through the Berkefeld filter, and all remained well; after an interval they were inoculated with the unfiltered culture, and one of them developed scarlet fever. The results appeared more rapidly than in the Schick test, and pseudo-reactions were more frequent, so that control on the opposite arm was of great importance. The lecturer showed coloured slides illustrating the typical Dick reactions. It was found that when a patient who had been inoculated contracted scarlet fever subsequently the area occupied by the previous positive reaction was marked by a paler area surrounded by a ring of intense rash. With regard to the reaction likely to be obtained, in the earliest stage of life a child apparently acquired a transient placental immunity from the mother, so that up to 3 months of age the Dick test was likely to afford a negative result. In the case of many hundreds of children from the congested slum areas Dr. Zingher found positive Dick tests in 32 per cent., whereas in better-class areas or country districts the proportion of positive reactions might be as high as 88 per cent. In a small proportion of inoculated persons constitutional symptoms, including a scarlatiniform rash, had been observed. In the case of 274 children recently retested at three institutions in New York 167, or 61 per cent., were

found to have become immune. No inoculated child admitted to hospital had so far contracted scarlet fever even though taken into the scarlet fever wards.

Speaking of the work already done on this subject in England, Dr. Copeman said that some research had been arranged at the South-Western Hospital, London, and elsewhere. The haemolytic streptococcus was found to be almost always present in the throat in cases of scarlet fever. Toxins had been prepared, and patients in the initial stages of scarlet fever were found to be positive; towards the end of the second week the majority of them became negative reactors, indicating immunity to the toxin. The medical officers' committee on scarlet fever, appointed by the Ministry of Health, came to the conclusion that it was desirable that further study should be undertaken under the co-ordinated direction of a team of expert clinicians and pathologists, and it was hoped that in time the resources of the Metropolitan Asylums Board would be available. Pending this, however, the committee decided to adopt a scheme, outlines of which were submitted by some of those working in the Ministry's pathological laboratory, and certain preliminary work was decided on. Meetings were held at Liverpool and Manchester, in each case with the medical officer of health and others concerned in the epidemiological service, and a meeting of all the research workers had been held at the Ministry's laboratory to ensure that the work carried out in the different laboratories should be on comparable lines. It was also resolved to apply the Dick test to patients admitted for scarlet fever to the Fazakerley Hospital, Liverpool, and the Monsall Hospital, Manchester. In response to a request specimen strains of the haemolytic streptococci of scarlet fever origin were sent from New York, but it was impossible for any agglutinating serum to be sent because it was being used in New York as fast as it was being produced. Reports of the work in hand were now being received, and at a later period a full official account of the work would be published. It would be premature to express any opinion as to the ultimate outcome, in view of the difficulties of such an investigation: the problems were much more complex than in the parallel work on diphtheria. Difficulties with regard to the specific identification of the micro-organism did not arise in diphtheria, but in scarlet fever, although a considerable body of evidence had accumulated to show that haemolytic streptococci were the responsible agents, the variety of the strains isolated had rendered it difficult as yet to determine whether one particular strain or any of several varying strains was specially responsible.

In conclusion, Dr. Copeman directed attention to the nature of the population which it was sought to immunize. Experience had clearly indicated in the course of work on diphtheria that where a certain general basis of immunity already existed it was comparatively easy to increase the extent of that immunity to a sufficiently high level. On the other hand, in certain institutions which for years had been free from this disease, because the children came in chiefly from rural areas, the immunity was found to be practically non-existent, and the building up of immunity was difficult and required a long time. It remained to be seen, from the work now proceeding at various centres in this country, whether the response to immunization work in scarlet fever would run on similar lines. He added that he had been greatly impressed by what he had learnt in New York of the practical working of the Dick test, and his opinion had not been altered to any appreciable extent by the use of the test in this country so far. But the attainment of anything like complete immunity appeared to be decidedly more difficult of accomplishment in scarlet fever than in diphtheria, and there seemed to be some reason for believing that any immunity thus produced was by no means permanent.

Dr. F. GRIFFITH supported Dr. Copeman's remarks by showing some lantern slides and specimens.

Sir WILLIAM WILLECOX said it was important that information should be afforded as to what was being done in New York, and also that research should go forward in hospitals in this country. He was on the staff of the

London Fever Hospital, which accounted for his interest in this matter, but, up to the present, no experimental work had been performed there on the Dick test. He was sure from what they had heard that it was a most valuable test in determining whether immunity was present or not, and it was a test of some value for diagnosis. With regard to the production of immunity, Dr. Copeman had made some interesting statements, but he had hinted that the length of time during which immunity was conferred was probably not very great. One point must be borne in mind when considering the production of immunity to these various diseases. If it was intended to immunize the child against scarlet fever by the method suggested the result would be to render the child anaphylactic to horse serum, and should the child later on develop diphtheria and require diphtheria antitoxin a rather difficult situation might arise. He thought the profession might go a little too far in using serums for immunization against all these various diseases. This applied particularly to scarlet fever, which in this country of recent years had had an extremely low mortality.

Dr. J. A. NIXON said that in Bristol the Schick test had given such ample satisfaction that all concerned were desirous of learning about the possibility of detecting susceptible and non-susceptible cases of scarlet fever also, and of immunizing the susceptibles. He was not in the least deterred by the dangers of anaphylaxis which Sir William Willecox had pointed out. During the war repeated doses of antitetanic serum were given to wounded men, with no untoward results. He was disappointed that the Schultze-Charlton reaction would not apparently be available for immediate diagnosis; he had hoped that this might afford help in difficult cases, but evidently the profession would still have to rely mainly on clinical signs.

Dr. E. W. GOODALL (North-Eastern Hospital) said that the scheme which the Ministry of Health proposed, and which would eventually bring in all the leading fever hospitals of the country, was the right one; hitherto similar work had been limited, to its disadvantage, to one or two institutions. He also made some interesting statements on anaphylaxis, and pointed out (as also did Dr. Copeman) that Sir William Willecox had been under a misapprehension. As Dr. Copeman stated, the material used should have no horse serum in it, and practically no protein, so that anaphylaxis was unlikely to occur.

Dr. BLAKE (North-Eastern Hospital) said that some work had been done at his institution, but so far the type of scarlet fever available had not been severe enough to furnish ground for a true test. Dr. F. THOMSON (North-Eastern Hospital) also said that he had been favourably impressed by the work so far as it had gone. Dr. W. MAIN suggested that scarlet fever arising in an epidemic form was something more than a streptococcal condition. The solid fact that emerged from this American work was that the rash was a streptococcal rash, and that the streptococcal element in scarlet fever was much more important than had been supposed. Sir WILLIAM HAMER said that he was rather in the position of the man in the New Testament: "I believe; help thou mine unbelief." He recalled that, forty years ago, Klein isolated from patients suffering from scarlet fever a streptococcus which he called the *S. scarlatinae*. It seemed as though there were periodical epidemics of belief that the organism of scarlet fever had at last been discovered.

Dr. COPEMAN, in reply, said that he was glad this work had brought into prominence again the work of Klein. He could remember the time when it was scoffed at, but it had a very sound basis. It was true that scarlet fever was not now a serious disease in this country, though it was quite possible that at some time in the future a wave of more virulent infection might arrive. But even as matters stood this American work was likely to be useful when the possible complications of scarlet fever were considered. It was well known that some of the most severe complications of a disease were not unlikely to follow an exceedingly mild manifestation of the disease itself, and in the case of scarlet fever such complications as otorrhoea, rhinitis, and nephritis were the bugbear of the epidemiologist.

## BACTERIAL URINARY INFECTIONS.

A MEETING of the Section of Urology of the Royal Society of Medicine was held on April 23rd, with the President, Mr. CYRIL A. R. NITCH, in the chair.

Professor LEONARD DUDGEON opened a discussion on bacterial infections of the urinary tract. He considered first a group of bacilli which resembled *B. paratyphosus* in appearance, but differing from that organism in being haemolytic. This infection clinically resembled paratyphoid and was often diagnosed as such. The causal organism could often be recovered from the intestine and proved by serological tests to be identical with that in the urine. The disease, though relapses did occur, was not so intractable as the chronic form of *B. coli* urinary infection. Vaccine treatment was generally contraindicated as the sufferers exhibited a remarkable hypersensitiveness. Charts were shown to illustrate the type of fever in untreated cases, and the effect of vaccines. The next organism to be considered was the *B. coli*, of which there were two varieties: A, haemolytic, and B, non-haemolytic. It was remarkable that 70 per cent. of coli urinary infections in the male were of the haemolytic variety, whereas in the female the proportion was reversed. He had no doubt that the origin of the infection was from the intestinal tract, and had frequently isolated an identical organism from the faeces and from the urine. Experimentally it was difficult to produce a urinary *B. coli* infection by intravenous inoculation, so long as there was no obstruction in the urinary tract. Vaccines were useful only in the haemolytic variety, and hypersensitiveness to vaccines occurred in many cases. Often after the acute symptoms had subsided, the organism was still present in the urine, and when relapses occurred it was almost always the same organism. From this he maintained that so-called re-infections were in reality relapses. *B. proteus* infections might be very severe. The bacilli could be recovered from the blood stream and the intestinal tract in addition to the urine, the latter becoming characteristically alkaline and containing large quantities of mucus, pus, and triple phosphates. Vaccines might be tried after the acute stage of *B. proteus* infection had passed off. The *Staphylococcus albus*, occurring in conjunction with pus in the urine, was an almost certain indication of the presence of a calculus.

Dr. E. LEPPER described a number of experiments in the production of lesions in the kidney by intravenous injection of *B. coli*. It was found that lesions could easily be produced if the ureter were obstructed for even a short time (experimentally this was done by means of an elastic band which produced no permanent effect upon the ureter), whereas no effect was produced by the injection of large doses of *B. coli* in the absence of obstruction. She concluded that compression of the ureter led to dilatation of the pelvis with engorgement and stasis, and minute haemorrhages from the veins. In these circumstances the organisms gained access to the renal tissue. Sections of the lesions produced in rabbits were exhibited on the epidiascope, some of which showed embolism of small arteries by solid masses of bacilli.

Sir JOHN THOMSON-WALKER, who discussed the diagnosis and treatment, referred first to the prodromal symptoms. For four or five days before a bacterial infection of the urine became manifest there was malaise, hypersensitiveness to heat and cold, irregularity of the bowels, and increased frequency of micturition. When the disease became established the frequency became great, and finally passed into the stage of strangury. There was a rigor, the temperature shot up to a high level, the urine became cloudy and not infrequently contained blood. The bowel was distended, there was obstinate constipation, and often acute abdominal pain. The kidney often enlarged so much as to give rise to a suspicion of pyonephrosis, which was especially to be suspected if the urine was clear. Localizing symptoms—such as pain in the loin, enlargement of the kidney or prostate—were present in the majority of cases, but occasionally were totally absent. The course of the disease was very variable, and relapses were common. Puzzling cases were: (1) those in which there was high

fever, often accompanied by severe nervous symptoms and no signs other than bacilluria; (2) those in which there was pain only—it was to be remarked that actual renal colic might occur in this disease without any calculus; (3) those in which haematuria was the main symptom; and (4) those in which the urine was sterile. Clinically three types of the disease were recognizable: (1) recurrent pyelo-cystitis, (2) cystitis, (3) bacilluria. The second was comparatively rare, since the real source of the trouble was often found in the renal pelvis. In 100 consecutive cases diagnosed as cystitis the urine from both kidneys was sterile in only 42; in 30 cases one kidney was infected, and in 28 cases both kidneys. The clinical type known as bacilluria was the variety which gave rise to chronic toxæmia, with fibrositis and various joint troubles: these cases were often regarded as being neurasthenics. The infection having its origin so frequently from the bowel, prophylaxis should start there. Drastic purgation, which removed the normal protective coat of mucus and possibly damaged the epithelium, was to be avoided. He had seen bacilluria follow drastic purgation, Plombières treatment, and occasionally the removal of a normal appendix. Urinary infections were apt to follow operations on the bowel and female pelvic organs. In such cases he advocated a preliminary course of urinary antiseptics as a prophylactic measure. The treatment of these conditions was governed by the reaction of the urine. Urotropine acted only in an acid medium, and in acute conditions there was little time for it to give off formalin as the bladder would not tolerate an acid urine. He had no experience of the new compound hexamethyl resorcinol. In alkaline urines methylene blue and certain other dyes, among them mercurochrome, exerted an antiseptic action, but were not nearly so powerfully antiseptic as urotropine in acid urines. He advocated washing out the renal pelvis only in cases in which there was no infection in the lower urinary tract, and no urinary obstruction, an exception to the latter being made in the pyelitis of pregnancy.

## METABOLISM AND THE SYMPATHETIC SYSTEM.

In the Section of Medicine of the Royal Society of Medicine on April 28th two communications were made—one by Dr. ERICH LESHKE, professor of medicine, University of Berlin, on metabolism and the sympathetic system, and the other by Dr. O. LEXTON, on a condition to which he gave the name of "hypoglycypresis." Dr. ROBERT HUTCHINSON presided.

Professor LESHKE began by saying that the whole interest of clinicians, pathologists, and physiologists of recent years had been absorbed in the study of the well marked and fundamental influence of the endocrine glands upon metabolism. At the time when he began his own experimental and clinical work on the hypothalamic centres of the autonomic nervous system and their influence on metabolism it seemed heresy to suggest that many troubles, like diabetes insipidus, dystrophia adiposo-genitalis, and some forms of glycosuria, might be of nervous rather than glandular origin. His line of research had, however, now been justified, and evidence had been brought together showing the importance of the role of the sympathetic centres in the diencephalon in the regulation of metabolism.

He spoke first of his search for clinical evidence as to the causation of diabetes insipidus. His work had led him to abandon the pituitary theory and to look for some other pathogenic factor. In clinical pathology the alterations which led to diabetes insipidus were chiefly those involving the infundibular region and the tuber cinereum. In one well known case of diabetes insipidus occurring after a gunshot wound, the bullet was found not in the sella but in this region. A few cases had been reported where diabetes insipidus arose after an attack of epidemic encephalitis; he had also seen the disappearance of diabetes insipidus after encephalitis, and it was known that epidemic encephalitis was a cerebral disease, not a glandular one. The frequent occurrence of diabetes insipidus after injuries to the skull was explained by the fact that the infundibular region was one of the most exposed parts of the brain to injury. He instanced the case of an officer who, after

a shell explosion, wounding his forehead, immediately developed bitemporal hemianopsia and persisting diabetes insipidus. In many of these cases diabetes insipidus persisted for life, and the presence of nervous troubles, with the absence of real pituitary symptoms, was in favour of the theory he had advanced—that is, the diencephalic as against the pituitary theory. He had dwelt perhaps somewhat too long on diabetes insipidus, but it seemed to him to afford an interesting example of the regulating influence of the autonomic nervous system on metabolism. Disturbance of this regulation led to polyuria, or, in slighter cases, only to diminution of urine concentration. It was of the greatest importance to make a thorough histological examination in cases of diabetes insipidus coming to autopsy. He had seen one case from his own clinic with normal hypophysis and exclusive degeneration of the supra-optic. Similar cases had been published in Paris. Histological examination in these cases would make for a better localization of the sympathetic "centres" (if it was allowable to use this inexact term) in the diencephalon or interbrain, and to establish their relation to the pituitary body.

Professor Leschke came next to a discussion of dystrophia adiposo-genitalis. There was hardly any part of the hypophysis or its neighbourhood which had not been thought of as furnishing the cause of this interesting anomaly. With regard to the posterior lobe, he had an impression, from animal experiments and from a case of isolated posterior-lobe destruction by an epithelioma, that it had not much influence either on growth or on metabolism. Destruction or atrophy of the anterior lobe nearly always gave rise to genital atrophy. Obesity following hypophysectomy had been observed by Cushing and others, but lesions of the infundibular region could not be excluded, the more so as Victor Horsley in his experiments did not obtain obesity. On the other hand, all the classical phenomena of Fröhlich's syndrome could experimentally be reproduced by mere lesion of the diencephalon between the tuber cinereum and the corpora mamillaria. The *post-mortem* findings in more than ninety cases clearly demonstrated how unsatisfactory the pituitary hypothesis was. In some cases the lesions had been found in the anterior lobe, in others in the posterior, in a third group in the pars intermedia and ductus infundibularis, and in more than twenty of the cases the pituitary gland had been found to be quite normal, or so slightly affected that it could not be regarded as impaired functionally. The pituitary theory, which formerly held the field, had now, he thought, weakened. His own view was that the diencephalic centres always played the foremost part in the development of dystrophia adiposo-genitalis, but he did not deny that the pituitary body had a great influence upon the function of these centres and that its internal secretion was indispensable, not only for normal growth and sexual development, but also for normal metabolism. It was more than probable that the sympathetic centres regulating metabolism and sexual development were not identical, though closely related. He mentioned one variation of dystrophia adiposo-genitalis which he had met with in four cases; this included a most characteristic skin pigmentation, hundreds of small naevi, like those of Recklinghausen's disease, from which the condition was distinguished by the absence of neurofibromata and the presence of signs of certain endocrine and sympathetic disturbances. This syndrome, which he was convinced was not uncommon, he proposed to call "dystrophia pigmentosa."

Finally Professor Leschke mentioned diabetes mellitus. It might seem wrong to associate the diencephalon with diabetes, now that the pancreatic origin of diabetes had been definitely proved by the success of insulin therapy, but pancreatic activity, like any other glandular function, was under the regulating influence of the sympathetic nervous system. He was convinced that disturbance of sugar tolerance and blood-sugar level was due to involvement of the interbrain rather than to the derangement of pituitary function. Among 180 cases of acromegaly he had found glycosuria or hyperglycaemia in 82. He had also found a true combination of diabetes mellitus and insipidus. The impairment of urine concentration was

hidden by the presence of sugar, which gave apparently normal figures of specific gravity. Both diabetes and obesity had been observed to develop after tumours and inflammations of the diencephalon and its base. There seemed no doubt that disturbances of the regulative function of the interbrain between the tuber cinereum and corpora mamillaria gave rise to lowering of carbohydrate metabolism and obesity, those of the corpus striatum to hyperglycaemia and glycosuria. His general conclusion was that a close relation existed between endocrine glandular activity and sympathetic nervous regulation. He pleaded for a more synthetical point of view, like that of the Hippocratic school in olden times, which had been neglected in the past century in favour of the analysis of symptoms. He was quite aware of the hypothetical character of many of the views he had expressed, but he thought it was well if at the base of scientific progress there was some imagination—and even some phantasy.

Dr. F. PARKES WEBER said that he had recently had the opportunity of examining a few cases allied to the rather rare types referred to by Professor Leschke. Since January, 1923, he had occasionally seen a man (Hebrew), then aged 39 years, with retinitis pigmentosa, obesity, and sexual impotence—an isolated (non-familial) case, and not a typical case of dystrophia adiposo-genitalis. His attention had been specially drawn to the subject by Solis-Cohen and Weiss of Philadelphia, who had published their family group of similar cases in the current number of the *American Journal of the Medical Sciences*. At a recent meeting of the Neurological Section of that society Dr. Douglas McAlpine had demonstrated an isolated case of retinitis pigmentosa with hypopituitarism and polydactylism in a boy, aged 15 years. Recently Dr. Adolphe Abraham had shown him a man, aged about 40, whose whole body was covered with small blackish pigment naevi (lentiginos), and who had a peculiar excess of the soft parts of his fingers and toes, with ulnar deviation and overextensibility of the fingers, but not the typical dystrophia adiposo-genitalis mentioned by Professor Leschke. He (the speaker) regarded this case as allied to Recklinghausen's disease and tuberous sclerosis of the brain, the patient having likewise a gradually progressive hemiplegia of the right side which might be explained in that way. The pigment naevi might be regarded as taking the place of the facial naevi of the adenoma sebaceum kind which had been noted in a good percentage of cases of tuberous sclerosis. With regard to the peculiarity of the patient's fingers and toes, he could not help thinking of the rare cases of clubbed fingers of congenital or early developmental origin, which might be familial; these he had recorded in the *BRITISH MEDICAL JOURNAL* in 1919 (ii, p. 379). With regard to the consideration of the two rare combination types just referred to, he drew attention to the following points: the retinitis pigmentosa might be represented by an atypical pigmentary degeneration of the retina; the dystrophia adiposo-genitalis might be incomplete and atypical; the symptoms of Recklinghausen's disease might also be incomplete and atypical; the other occasionally associated developmental abnormalities, such as polydactylism or congenital malformation of the heart, might be various in kind or degree. He believed that the association of polydactylism with definite or incomplete dystrophia adiposo-genitalis and retinitis pigmentosa was to be regarded as analogous to the occasional association of congenital cardiac abnormalities with mongolism.

Dr. W. LANGDON BROWN was inclined to general agreement with Professor Leschke's view as to the part played by the hypothalamus—all the observations of recent years tended in that direction—but it was quite possible that the pituitary was the mechanism through which the hypothalamus acted. It was well known that pituitrin was a powerful antidiuretic. Injected into the blood stream it would hold up the excessive output of urine for a considerable time. Was it probable that this glandular structure would have been placed in such close relation with the hypothalamus if there was no functional connexion also? The pituitary was quite capable of acting without the nervous system, but he would suggest that it was put into action through that system, and that some of the difficulties

encountered in interpreting results were capable of being resolved along the lines of that hypothesis. One of the great difficulties in all these pituitary cases was the very partial grouping of the symptoms. It was well known how extraordinarily varied the grouping of symptoms might be in what appeared to be pituitary lesions, and he thought that Professor Leschke's suggestion that a great deal of the regulation of the water metabolism was governed by the balance between the tissues and the blood was in harmony with the general trend of physiology. He recently had a case which came for treatment for diabetes insipidus. No pituitary lesions were found. Some months afterwards the patient came up again for cerebral symptoms, obviously tumour, probably pituitary, and at that time she had only a very moderate polyuria. This patient ultimately died, and was found to have a tuberculoma of the pituitary body. It was an interesting fact that the first suggestion as to the nature of the lesion came from the diabetes insipidus. That case, of course, did not prove or disprove the theory, but it showed that as the lesion advanced in the pituitary the diabetes insipidus became a less marked feature. He was quite prepared to believe that a great many of these effects came about through the sympathetic nerves, like the association of the pineal gland and sexual precocity, which was not an endocrine association at all, but probably came about through nervous structures. He felt that there had been rather too much made of the pancreatic theory. He would have preferred to put it, so far as the pancreas was concerned, in this way, that not all cases of diabetes were pancreatic in origin, but that they would become pancreatic if the hyperglycaemia was allowed to persist. He was interested to find that Professor Leschke had evidence pointing in this direction. As to the association between diabetes mellitus and diabetes insipidus, it had been a common observation for the last two years that insulin very often, while stopping the glycosuria and checking the hyperglycaemia, did not check the polyuria. That was a further fact pointing to the pituitary origin of some cases of diabetes mellitus.

#### "HYPOGLYCOPYRESIS."

Dr. O. LEYTON, in explanation of his title, said that in the past diseases had been named either after the men who had described them or after their most prominent symptom or symptoms. He instanced the diseases to which the names of Basedow and of Graves had been attached. The disadvantages of calling a disease after a man were that it added to the burden of the memory and also that it led to confusion in different countries, where different names were adopted. Certain disadvantages also attached to the naming of a disease after the most prominent symptom, because at the beginning of the disease the symptom might not be present. Diabetes mellitus owed its name to the two signs—polyuria and glycosuria. The onset of diabetes might be insidious or acute. At present there was no proof that those cases which appeared to be acute were not really insidious, and had been aggravated by some toxæmia. When the onset was insidious there was a stage when there was no polyuria or glycosuria, but only a slight diminution in the efficiency of the carbohydrate metabolism. Such cases, he suggested, might be called by the term "hypoglycopyresis," meaning a diminution in the burning of sugar. He admitted that it was a cacophonous term, but he was open to hear suggestions for a better. An early "hypoglycopyresis" had neither polyuria nor glycosuria unless the patient underwent some pancreatic "orgy." The question naturally arose, How was the condition recognized if there was no polyuria and no glycosuria? One hoped that in the future it might be possible to recognize "hypoglycopyresis" in the descendants of diabetics, especially in obese descendants; the recognition of the condition would permit of advice being given whereby the disease might be arrested. The method adopted for recognizing this deficiency in the carbohydrate metabolism was to give injections of glucose. Dr. Leyton described his plan of injecting a measured amount of dextrose intravenously, and said that, although cumbersome, it was to be preferred to administration by the mouth, because oral administration led to many fallacies, and in addition the other method was better from the point of

view of the time factor, which was important. But he must warn those who gave intravenous injections of dextrose to be careful to obtain pure dextrose and to be punctilious in technique. He gave in detail observations on two cases, which he illustrated by curves. The second and perhaps more interesting of these cases came his way because the patient had a low renal threshold. Sugar had been found in his urine six months before he came under his observation, but he had no thirst to speak of and he never had polyuria. The examination for the blood sugar showed that it was not a case of diabetes mellitus, but his blood sugar rose to a certain extent after a sweet meal. It was found that his carbohydrate efficiency was 75 per cent.; in other words, he suffered from "hypoglycopyresis," not sufficiently to cause thirst or polyuria, but sufficiently to cause hyperglycaemia after the absorption of sugar in large quantities. This patient had a duodenal ulcer, and was operated upon, and on the sugar in his blood being tested some three months after operation he was found to have developed something approaching to diabetes, probably owing to the anaesthetic given him at the operation—for it was found as a rule that an anaesthetic permanently depressed the carbohydrate metabolism in mild diabetes. Dr. Leyton concluded by saying that this case and the other seemed to him to prove that there was a condition of depressed carbohydrate metabolism long before there was any true diabetes mellitus. The question was, What should it be called?

Dr. PARKES WENGER asked whether there was any relation between these cases and cases of renal diabetes—whether the two had ever occurred together. Dr. LEYTON replied that he did not think the one protected against the other. The reason one investigated these cases was because the threshold was low, but one could come across cases of so-called renal glycosuria with normal sugar-burning.

#### DIAGNOSIS OF THE DYSPESIAS.

At a meeting of the Bristol Medico-Chirurgical Society on April 8th, the President, Dr. J. O. SYMES, in the chair, Mr. A. RENDLE SHORT read a paper on the diagnosis of the dyspepsias.

Mr. Rendle Short's observations were based on a series of 100 cases of non-malignant dyspepsia, all studied on a definite plan, verified by operation, and mostly followed up subsequently. Increased accuracy in the diagnosis of dyspepsia was due to better knowledge of physiology, disregard of haematemesis as a diagnostic point, watching the movements of the bowel by means of an x-ray screen, and better classification. It was now known that both the hypersthenic and the hypotonic types of stomach might exist in perfectly normal persons. In the former type the viscus emptied quickly; the patients were apt to have an excess of acid, and were "hungry folk." On the other hand, achlorhydria was not necessarily a sign of disease any more than was visceroprosis. It was now known that a nervous reflex mechanism controlled the sphincters of the alimentary canal, so that delay in any one part might cause general disturbance, producing symptoms referred to a region distant from the actual site of the disease. The minute lymph nodules, found especially along the lesser curvature of the stomach, might ulcerate and bleed. Haematemesis might be the only symptom of disease; or there might be dyspepsia due to causes outside the stomach and duodenum, and accompanied by a dangerous bleeding; or, finally, there might be bleeding from a chronic ulcer. In the series 1 in 3 of the gastric and duodenal ulcers were accompanied by bleeding, and 1 in 6 of the cases of appendicular dyspepsia. Mr. Rendle Short classified dyspepsias as functional, organic, or reflex. The functional type was not hysterical, but implied a disturbance of function, as with the acute and chronic gastritis of alcoholism, dyspepsia of phthisis, anaemia, and anorexia nervosa; all these were the province of the physician and were curable by medical means. The reflex dyspepsias were: (1) Gall-bladder dyspepsia, flatulence and vomiting being prominent, the vomiting coming especially after certain foods. Treatment with alkalis was unavailing, and there was often some gastric delay. (2) Appendix dyspepsia; pain was usually not very severe,

but continuous and worse after food, the patients often vomiting without relief of pain. (3) Undiagnosable reflex dyspepsia—pain and vomiting were not related to each other or to food. Organic disease of the stomach or duodenum might give rise to several types of dyspepsia: (1) Gastric ulcer. A definite sequence was usual, thus: food, relief, pain, vomiting, relief. The relief following a meal tended to be rather over half an hour. The pain was severe and vomiting the rule. A test meal was useless in diagnosis, but x rays might give great help. If, later, pain became continuous and was felt in the back, pancreatic involvement might be suspected. (2) Duodenal ulcer. Vomiting was less common, only half the cases showing it. Relief obtained by food was usually over an hour. The pain was severe, the test meal of little service, though hyperchlorhydria was the rule, and deformation of the skiagraphic duodenal cap was characteristic when present. The stomach usually emptied quickly unless stricturing had ensued, but this was a cause rather than a consequence of the ulcer. (3) Duodenal ileus might occur by itself or be a symptom of other disease: flatulence and nausea were marked, vomiting common, pain not severe, and the relation to food was obscure. The skiagram might be definite, showing great delay and distension in the second and third parts of the duodenum; duodeno-jejunostomy cured the condition. (4) Periduodenal adhesions might give rise to severe pain, even after taking water; vomiting was usual, bleeding absent, and the x rays showed gastric delay. (5) Gastric cancer was accompanied by great loss of appetite, and pain might be continuous. A test meal might show nothing, but x rays might reveal a typical deformity. (6) Pyloric stenosis, hour-glass stomach, or leather-bottle stomach might account for dyspepsia. Mr. Rendle Short showed a number of skiagrams illustrating his paper.

#### *Diagnosis of Nasal Sinus Disease.*

Dr. P. WATSON-WILLIAMS read a note on some points in the diagnosis of nasal sinus disease, showing how it was possible to differentiate between cells, using the suction-syringe method of sinus exploration. Especially might this become important when one sphenoidal sinus was very large and the other small. The large sinus might be entered from the opposite side of the nose, in mistake for the sinus of that side, and the latter thus overlooked. In certain cases, notably those with involvement of vision, this might lead to serious errors in diagnosis. The point was illustrated by a collection of lantern slides.

### ROYAL ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Section of Surgery of the Royal Academy of Medicine in Ireland was held on April 3rd, with the President, Mr. R. C. B. MAUNSELL, in the chair.

#### *Jejunostomy in Acute General Peritonitis.*

Mr. SETON PRINGLE read a paper on jejunostomy in acute general peritonitis, and referred to a previous communication in which he had advocated this operation; he stated that his recent experience had confirmed his opinion of its usefulness. He disagreed with Sampson Handley, who had recently stated that jejunostomy was inadvisable because it entailed a loss by the patient of great quantities of fluid, and required a second operation for its closure should the patient survive. From his own experience Mr. Pringle confidently asserted that neither of these objectionable results would follow a jejunostomy performed after the manner advocated by C. H. Mayo.

Mr. H. STOKES said that the procedure described by Mr. Pringle had been adopted in the Mayo Clinic about five years ago, and unquestionably in a great many cases it had been very efficacious. He had found some difficulty in getting the tube to drain. At present he had a patient on whom he had operated for septic peritonitis from perforation, using the method described. The patient was going on splendidly, and had never vomited since the operation.

Mr. A. K. HENRY asked whether the operation should be limited to cases in which there was a localized peritonitis,

or where pelvic peritonitis was more definite than abdominal peritonitis.

Mr. C. J. MACAULEY said that jejunostomy had been advocated by Victor Bonney and Sampson Handley for some time. The intestine should be followed up until a heavy coil was found; if this was done there should be no difficulty in getting the tube to drain. He drew attention to the remarkable effect this method had in stopping vomiting. The opening must be made in such a way as to encourage spontaneous closure after removal of the tube. In some cases of pelvic peritonitis the obstruction did not cease with the subsidence of the peritonitis. The success of jejunostomy in these cases depended on the absorption of pelvic exudate and the power of the intestines to empty themselves. It was useless to relieve the mechanical obstruction in bad cases unless jejunostomy was performed at the same time.

#### *Dislocation of the Semilunar Bone.*

Mr. R. A. STONEY read a note on a case of dislocation of the semilunar bone, and showed a specimen.

The patient was a man, aged 40, who dislocated the semilunar bone as a result of the backfire of a motor car. The case was not seen until five months after the accident. Distinct antero-posterior thickening of the wrist was present without relative change in the position of the styloid processes of the radius and ulna. There was considerable disability, and teno-synovial creaking was obtained on the front of the wrist when the patient flexed the index finger. The bone was removed by an anterior incision; passive and active movements were commenced on the second day after the operation.

Anterior dislocation of the semilunar had been mentioned by Eriksen in 1872, and by Taffe of Brighton. Since that time several cases had been described, many of them associated with fracture of the scaphoid. The semilunar bone alone among the carpal bones had a larger palmar than dorsal non-articular surface, and consequently the bone was wedge-shaped, with the base anteriorly. In forced hyperextension of the wrist the bone was liable to be shot out between the lower end of the radius and the second row of the carpal bones. The diagnosis might be made by detecting antero-posterior thickening of the wrist, partial flexion of the fingers, and possibly tingling in the distribution of the median nerve in the hand; it was confirmed by a lateral x-ray examination of the wrist. If recognized early it might be possible to reduce the dislocation under an anaesthetic. If the diagnosis was not made until late it would probably be necessary to remove the bone in order to relieve the disability.

Mr. C. J. MACAULEY thought that sometimes considerable disability in the wrist arose because the diagnosis of dislocation of the semilunar bone was not made. All cases of this sort should be carefully x-rayed, because a good deal of trouble might be avoided if the patient was made to realize at the beginning that he had something more than a sprained wrist which would be healed in a few days. He thought there was no question that excision was the right treatment if the dislocation did not yield to manipulation.

#### *Surgical Exposure of the Radius.*

Mr. A. K. HENRY described (1) a complete exposure of the radius, (2) an exposure of the second stage of the vertebral artery, illustrating his account with anatomical preparations. In the complete exposure of the radius the skin and deep fascia were divided by an incision extending from the distal end of the biceps to the radial styloid. The biceps tendon was exposed, and a finger passed along its radial border met the loop of the recurrent radial vessels; this was divided. The three long muscles which flanked the radius could then be retracted outwards, exposing the lower part of the shaft. The upper third was exposed by peeling the supinator brevis from the bone. Division with the knife of the bicipital bursa just external to the biceps insertion gave sure access to the edge of this muscle, which skirted the bursa, but was obscured by fat and areolar tissue. The posterior interosseous nerve lay between two layers of the supinator brevis, and was raised with it by the rugine.

Mr. R. A. STONEY thought the first demonstration would be of more frequent use to surgeons than the second. The

second was extremely interesting, but he did not think it likely that many of them would often be required to perform this operation, whereas exposure of the radius was an operation which might be necessary at any time. It was very helpful to have a simple method by which injury to the posterior interosseous and radial nerves could be avoided with certainty. This was a point of very considerable surgical importance.

Mr. A. CHANCE said that, Mr. Henry's previously described methods of exposure of the humerus and femur having proved excellent in practice, he was particularly interested in Mr. Henry's suggestion regarding exposure of the radius, since he had under his care a case of new growth of the radius for which he contemplated local excision. Removal of a portion of the radius was most frequently required for fractures of the head of the radius, and he had been in the habit of adopting a posterior incision.

Mr. HENRY, replying, did not think the method he had described would be a good one for exposing the head of the radius; it was intended as a method of exposing the entire shaft.

### LEGAL RESPONSIBILITY OF THE SURGEON.

LORD JUSTICE ATKIN presided at a meeting of the Medical-Legal Society, held in London on April 25th, when Lord RIDDELL read a paper entitled "The legal responsibility of the surgeon."

Lord Riddell said his object was to offer a few observations regarding certain problems of surgical responsibility in the light of modern ideas. By the wording of the Draft Criminal Code of 1880, everyone, whether a licensed practitioner or not, was protected from criminal liability for performing with reasonable care and skill any lawful surgical operation on any person with his consent, and for his benefit, providing that the operation was reasonable, having regard to the patient's state at the time, and to all the circumstances of the case. Consent might be given by the patient's guardians or relatives, if the patient was incapable of himself consenting. The extent of the consent must not be exceeded. In cases of emergency, however, the person about to perform the operation might act on his own responsibility. This exception applied when in the course of the operation the surgeon found it necessary in the patient's interest to go beyond the consent given. The rules were the same in civil proceedings for negligence, but the interpretation of reasonable care and skill was more stringent, and the consent of the patient might absolve the person performing the operation from civil liability. *Prima facie*, the rule as stated seemed fairly plain, but the application of general principles was often an elusive task. For instance, an abortion was an illegal operation unless the life of the mother would be endangered by allowing her to go her full time. Mortality with regard to a certain operation might be, say, 97 per cent.: was the surgeon justified in operating after explaining the danger to the patient? And would such operation on a dying man be justified, and yet improper in the case of one whose condition was not so grave? If the surgeon was satisfied that the operation would not save a dying patient's life, was he justified in performing it to please the patient? It was obviously impossible to lay down general rules for these cases.

During recent years the public and the medical profession had been faced with new problems arising partly out of the study of eugenics, partly out of new obstetrical and surgical discoveries and methods, and partly out of the aims and aspirations of modern men and women. These might be propounded by the question, "In what circumstances was it legally and technically justifiable to sterilize a man or woman?" Needless to say, no surgeon was bound to perform such an operation. There was a widely prevalent idea that, apart from illegal abortion, a surgeon and patient were entitled to agree upon any operation, and that if death resulted the consent of the patient relieved the surgeon from responsibility. That was erroneous. The validity of the consent depended upon the nature of the operation. A man might not maim himself or arrange with another person to maim him. To-day interest centred

around vasectomy, which was, he was told, not uncommon in certain circles when married couples did not wish for offspring owing to the state of health of husband or wife, or for economic reasons, or because of the husband's family history—for instance, a strain of lunacy. In law such operation amounted to "maiming." The sterilization of women was a much more frequent operation, and the questions involved were of wide and growing importance. The law regarding operations on women was not so clear as that relating to men. He thought such an operation was illegal if performed upon a healthy woman, consent or no consent. The continuation of the race was a matter of public policy, and the sterilization of women to gratify a mere caprice would appear to be contrary to the public welfare and therefore illegal. The surgeon was faced with the difficult problem as to whether the operation was justifiable as a prophylactic measure to avoid a pregnancy or series of pregnancies, certain to be difficult or dangerous. It must be remembered that other methods of avoiding conception were available, including, of course, self-restraint.

Furthermore, what degree of threatened danger, or discomfort, justified the operation, and was it justifiable when the pathological condition was one that might not be permanent—for instance, a weak heart? What was the surgeon to do when appealed to by a workman's wife, who stated, in effect, that she had only three alternatives: (1) repeated pregnancies of a trying and dangerous character; (2) a sterilizing operation; (3) the loss of her husband? Most people would agree that there was nothing contrary to public policy in performing the operation in these circumstances. Then there was the still more difficult case of the woman who had had, say, five children in five years. The strain on her health had been severe, and the husband's financial position made it undesirable, in the interest of herself and her family, that she should have more children. She was anxious to be sterilized. Was the surgeon justified in performing the operation? Was the patient's general state of health and the prospect that it would become worse if she again became pregnant a pathological condition justifying sterilization? It would be interesting to know what medical evidence of justification, or otherwise, would be forthcoming in the event of a prosecution for manslaughter owing to a sterilizing operation. It was just as well that the subject should be ventilated. The public was entitled to know what was happening and what opinion the medical profession held. An interesting question arose as to whether the husband's consent was necessary if the wife herself consented. Supposing he would not consent, or, for some reason, his consent was not obtainable, what course was to be taken? A husband might well have a cause of action against his wife and the surgeon for depriving him of the possibility of offspring. It seemed clear that the husband would have no claim in respect of such an operation when rendered necessary by definite pathological conditions.

Then the sterilization of the mental defective was a favourite plan of eugenicists. It was certainly alarming to learn that there were some 13,000 mental defectives in the United Kingdom, and that in twelve workhouses in one part of England twenty-three mentally defective women had had between them at least fifty-one children. Was sterilization legal in such cases? He considered the reply must be in the negative, unless the operation was for the benefit and welfare of the patient. The patient's consent would not justify the operation, even if he or she had sufficient mental capacity to give a valid consent. It was also clear, he thought, that the parent, or guardian, had no power to consent in such cases.

Lastly, the speaker touched on the legality of some of the so-called cosmetic, or beauty parlour, operations. The law seemed to be that such operations were not illegal, as they were not "maiming" operations. But here again the question of consent came in. Was a wife entitled to disfigure herself as she thought fit? If the beautifying operation turned out badly, could the husband sue his wife and the surgeon for damages? Was the wife's consent a bar? In short, could she do what she liked with her own face? There was this consolation for the surgeon—that if death resulted the action must be brought under the Fatal

Accidents Act, usually called Lord Campbell's Act, which provided that the representatives of the deceased had only the same right of action that the deceased had possessed. Thus, modern surgical methods and modern desires had raised new problems demanding the thoughtful attention of lawyers and surgeons, although happily in practice they rarely demanded solution.

### DIAGNOSIS OF PULMONARY TUBERCULOSIS.

At a recent meeting of the Royal Medico-Chirurgical Society of Glasgow, the President, Professor ARCHIBALD YOUNG, in the chair, Dr. IAN STRUTHERS STEWART of Nordrach-on-Dee spoke on "Some points in the diagnosis and prognosis of pulmonary tuberculosis."

Dr. Stewart referred briefly to the pathology in relation to the infection and subsequent spread of the disease. The infection at first attacks the lymphatic system; in the less acute cases the route may be through the tonsil to the cervical, mediastinal, bronchial glands, and thence by way of the peribronchial lymphatics of the larger bronchi to the lung, the subpleural lymphatics, and the visceral pleura. The inflammatory changes which take place in the bronchial wall as a result of the infection of the peribronchial lymphatics may be followed by caseation, ulceration into the lumen of the bronchus, and infection of the lung, or by blocking of the lumen with subsequent collapse of the lung area supplied—a condition which favours the further spread of the disease. Referring to the comparative frequency of the early signs and symptoms, Dr. Stewart gave the following percentages of frequency in 200 consecutive cases: cough 60 per cent., lassitude 48 per cent., pyrexia 42 per cent., hæmoptysis 27.5 per cent., pleurisy 24.5 per cent., loss of weight 12 per cent., loss of voice 8 per cent., night sweating 7 per cent., dyspepsia 3.5 per cent., neurasthenia 1 per cent. Dividing these into toxæmic and localizing symptoms emphasized the fact that the toxæmic symptoms—namely, lassitude, pyrexia, loss of weight, night sweating, indigestion, and neurasthenia—might appear before any physical signs could be detected. The importance of accurate observation of the temperature was urged, and several illustrative charts were shown. The speaker went on to correlate the signs and symptoms with the pathological changes. When the infection was spreading through the lung it might be that the only signs present were loss of expansion—more obvious above the nipple or in the axilla—with some faintness of breath sounds on one side. Narrowing of Krönig's area of resonance over one or both apices might be found, or diminished tidal expansion at one or other base. Dullness was not usually demonstrable at this stage, but a few fine crepitations, audible only after coughing, under or above the clavicle or external to the nipple, or in the interseapular region, ought to be viewed with suspicion. As the swelling of the bronchial wall increased the breath sounds became harsh, and this harshness was more easily detected in inspiration. With the bronchopneumonia dullness appeared, often detected more easily high up in the axilla. Broncho-vesicular breathing now appeared, becoming more bronchial as the consolidation increased. To detect the earliest evidence of pulmonary tubercle both percussion and auscultation must be used in conjunction with systematic inspection and palpation.

THE annual general meeting of the International Society of Medical Hydrology took place in Paris on April 20th and 21st, and was attended by the representatives of eight countries. Dr. Gustave Monod (France) was elected president for the year, in succession to Dr. Fortescue Fox (England). On the motion of Dr. VAN BREEMEN (Holland) a committee was appointed to report upon the incidence of chronic rheumatic diseases in Northern Europe and upon their treatment by physical methods. The following subjects were discussed in Professor Carnot's laboratory at the Faculté de Médecine: (1) Insulin treatment in relation to medicinal waters, introduced by Drs. CHABANIER (France), POULTON (England), and ERSTEIN (New York); (2) the spa treatment of rheumatism of traumatic origin, introduced by Drs. SCHMIDT (Czechoslovakia) and VINCENT COATES (England). Demonstrations and lectures were given by Dr. LÉPAGE and Professor DESGREZ.

## Reviews.

### SIR WILLIAM OSLER'S LIFE.

THE eagerly expected *Life of Sir William Osler*,<sup>1</sup> by his distinguished pupil, Professor Harvey Cushing, now of the Peter Bent Brigham Hospital, Boston, Massachusetts, has appeared within four and a half years of the beloved physician's death, and has obviously been a labour of love carried out with affectionate care. The story of one whose admitted motto was "Write me down as one who loves his fellow men" has been written in fragments by many hands, and his "Counsels and Ideals" have been collected by Dr. C. N. B. Carnae, but here it is sympathetically told as a well balanced whole. Early in 1920 there was a widespread wish for such an account of the manifold activities of the late Regius Professor of Medicine at Oxford, and by Lady Osler's wish this task was undertaken by Professor Harvey Cushing, who has cheerfully and unsparingly devoted the intervening years to this pious trust. Helped by letters to and from many sources and by Sir William's private pocket-books, for he was an inveterate note-taker, the *Life* is skilfully allowed to tell itself, and the recorder stands modestly back in the shade, as it were, allowing very little light to fall on his association, close as it was; thus the reader is left to speculate about the identity of the "someone" who, when "the Chief" finally left Baltimore in May, 1905, "unscrewed and took away the unpretensions Dr. Osler doorplate." It is rather a striking coincidence that perhaps the most successful medical biography, that of Lord Lister by Sir Rickman Godlee, who has just passed beyond these voices, and now the life of a physician and scholar, are both the products of surgeons' skilled pens.

The book, which is pleasantly written, contains an immense amount of new information, especially about Osler's early days, when he was an athlete and a prefect at school, a keen scientific naturalist, and withal a very human boy; much of it will not only interest but surprise many who, like the reviewer, fancied that they knew a good deal about his doings. A striking feature is the number of unexpected changes and chances of his career that are brought out. He was born in 1849, the eighth of a family of nine, and was to have been named Walter Farquhar, but as his birthday was on July 12th the assembled Orangemen, when shown the new arrival in the arms of the Rev. F. L. Osler, of far-off Bond Head in Upper Canada, insisted that he should be dubbed "William the young Prince of Orange." Later William gave up the idea of caring for souls for the cure of bodies, and in 1872 was anxious to join the Indian Medical Service; soon afterwards he was inspired by Sir William Bowman's example to be an ophthalmic surgeon, hoping to be able to devote his spare time to science. But on Bowman's advice he first spent seventeen months in physiological work at University College under Burdon-Sanderson, whom by a curious turn of fortune's wheel he succeeded thirty-four years later in the Regius Chair of Medicine in Oxford, a possibility which, had it ever entered the heads of a professor of physiology and his pupil with ophthalmological ambitions, would have seemed highly improbable. While thus in London his kindly teacher, Dr. Palmer Howard, Dean of the Medical Faculty at McGill and now widely remembered from the dedication in Osler's textbook, wrote to him explaining the conditions which as the pupil said, "blighted his prospects" as an eye specialist in Montreal. A little later he was offered, perhaps as a consolation prize, a lectureship on botany, but this he had the strength of mind to refuse, and eventually he adopted Palmer Howard's earlier advice "to cultivate the whole field of medicine and surgery, paying special attention to physiology," by, as is well known, accepting the lectureship in Montreal upon "the Institutes of Medicine," as physiology was termed after the Edinburgh fashion. Another feature, not so unfamiliar as some of these incidents to his later-day friends—his

<sup>1</sup> *Life of Sir William Osler*. By Harvey Cushing. In two volumes. Oxford: The Clarendon Press. 1925. (Med. Rev. Vol. I, pp. xiii + 685, 23 plates; Vol. II, pp. x + 768, 21 plates. 37s. 6d. net the 2 volumes.)

irrepressible fun, not to say practical joking—is described: for example, in his creation of Egerton Yorrick Davis, M.D., late U.S. Army Surgeon, of Fort Desolation in the Great Slave Lake District, and afterwards of Caughnawaga, a small hamlet on the St. Lawrence opposite Montreal, on whom he fathered fantastic stories, to whom he attributed even published letters, whose name he took when wishing to be unknown, and who indeed was to him as M<sup>c</sup>Conachie is to Sir James Barrie.

These two volumes are divided on a chronological and geographical basis into three periods, dealing respectively with his life in Canada (1849-1884), in the United States, first at Philadelphia as professor of clinical medicine in the University of Pennsylvania (1884-1889), then as physician-in-chief to the Johns Hopkins Hospital, Baltimore (1889-1905), and lastly at Oxford (1905-1919). The Johns Hopkins appointment was practically in the gift of J. S. Billings, who, an illuminating footnote allows the reader to guess, was converted, by the opinion of Professor W. H. Welch, from a leaning towards the late "Sir Lauder Brunton or a German professor who had been at the German Hospital in London," and is probably not named as he is alive. More than half of the first volume is devoted to the stirring sixteen years at the Johns Hopkins Hospital, where, to mention a later personal trait, he was beginning to be thoroughly steeped in medical history and "his infection with bibliomania was becoming chronic." The Osler most intimately known to his Johns Hopkins pupils was met at informal meetings on Saturday nights, when he would discuss the week's work and then give an appreciative talk, illustrated by early editions, on one or two of his favourite authors, perhaps Sydenham one week, Fuller or Milton the next, a practice he continued at Oxford. His unusual talent as an inspirer of youth was now for the first time appreciated to the full, and his success was far less due to his thorough familiarity with the subject-matter than to his knowledge of young men. What with teaching, practice, and his textbook, which first appeared in 1892 and was frequently revised with a remorseless hand, the days were very full and "he knew no idleness." But he had in a remarkable degree the power of economizing time; "no one could speak to Osler consecutively against his will," for he escaped by magic, but so graciously that those left could not feel any irritation. Though working at high pressure he wisely took holidays, often in England, and from 1894 was a frequent attendant at the Annual Meetings of the British Medical Association, and continued the custom after making his permanent home in this country; he became a member of the Central Council in July, 1905, and took a considerable part in the special clinical meeting in April, 1919, in London "under the Presidency of his brother Regius of Cambridge, for which reason Osler would have attended if for no other." He was also, as would be natural, chairman of the Oxford Division of the Association, and President of the Oxford and Reading Branch from 1919 until his death, but these are only two out of the numerous responsibilities he discharged. To the Baltimore period belongs the interesting photograph of Professors Howard A. Kelly, Osler, and W. S. Halsted, under one copy of which Osler characteristically wrote the appropriate legend: "The Fates: Howard A. Clotho, Wm. Lachesis, W. S. Atropos; the obstetrician holds the distaff; the physician spins the thread; the surgeon cuts it off."

The second volume is rather the larger of the two and has as its frontispiece an attractive and now sadly reminiscent photograph of "father and son," taken in June, 1905, by Dr. A. C. Klebs, an ardent bibliophile after Osler's heart. It deals with the years from 1905 until his untimely death on December 29th, 1919; the heading "The Oxford Period" is no doubt geographically correct, but "in England" or "in Great Britain" would in some respects be better, for, as the text amply shows, his influence and elsewhere whenever there was any work being done or a good cause to be helped. That Professor Cushing-period proves the indefatigable nature of his piety, but it is undoubtedly difficult always to sound the right note, and there is a subject on which, after some hesitation on

account of unavoidable personal bias, I feel a few words should be said. There is some very frank and superior criticism of the Royal College of Physicians of London, the expediency of which, as it is Professor Cushing's opinion, it would be wasting words to discuss, but the following extract deserves consideration, for it concerns some matters of fact:

"It has been seen that Osler was made a Fellow in his Montreal days and subsequently gave the Goulstonian Lectures; and if the College did not receive him twenty years later with open arms doubtless it was because enthusiasm over a newcomer would forfeit its dignity. Moreover, no practising physician or surgeon can be transplanted to another community without provoking some misgivings on the part of those who dislike new ideas or a picture him as a possible rival. But Osler never heeded prickles. He had lived for five years in Philadelphia with Peck and kept on the friendliest terms, and would not have recognized jealousy had he met her, green eyes and all."

Now Osler arrived in Oxford in May, 1905, and was Harveian Orator, which Professor Harvey Cushing describes as "the blue-ribbon event of British Medicine," in 1906, Lancelian Lecturer in 1910, and in 1915 declined an invitation to deliver the FitzPatrick Lectures; there real does not appear to be any evidence of a cold reception of this; but the unpleasant touch in the quoted paragraph the suggestion of jealousy and possible rivalry. This never suspected or saw any evidence of, but, being uncertain of the personnel of the "old brigade" to whom reference is made, I have inquired from others, and the almost identical reply has been, in some surprise, "No one could be jealous of Osler." Surely Osler and many of his friends would have preferred silence on such a matter.

Optimistic in his wisdom, Osler often curbed the fancy and exaggeration of new ideas: thus he published a paper with the paradoxical title, "On the advantages of a trace of albumin and a few tube casts in the urine of certain men above 50 years of age" (1901), and again in 1912 wrote "On high blood pressure: its associations, advantages, and disadvantages." His *Aquinitas*, containing the charming lay sermon on "Unity, Peace, and Concord," his farewell to the medical profession of America should be added to the list of books for a medical student's bedside library, for we are, or should be, students all our days. The account of the Oxford period is no doubt long but so full of incident that the interest is well maintained and is a tribute to the skill with which the *Life* has been carried through. Though the professional work of Sir William is well recorded it is never obtruded, and the well drawn picture presents the man and his personal charm rather more prominently than the great physician and pioneer in medical education in its broadest aspects; and this is as his friends—and they are many—would have it.

Osler's activity in promoting public health measures is regarded by Professor Cushing as the greatest of his professional services; thus from his early days in Montreal he was much engaged in a crusade against enteric fever, combining this with campaigns against malaria and tuberculosis in Baltimore and in England with a whole-hearted energy in the fight against venereal disease. The diminution in the incidence of enteric fever in this country did not allow him to forget its importance in war, and in the autumn of 1914 he addressed the officers and men in the camps at Churn (BRITISH MEDICAL JOURNAL, 1914, ii, 569) on "Bacilli and bullets," as an educational warning that in previous wars infection had always been a greater destroyer of life than the enemy, and later in the war he pleaded in most moving words for the adoption of means to prevent venereal infection of young men on leave from the front. But it might appear to some that Osler was pre-eminent as an educator of medical men, that, in fact, he so raised the standard of teaching and practice that the striking change in the character of medicine in America during the last forty years was largely due to his influence and inspiration at the Johns Hopkins Hospital; for such a stimulus acts on the medical profession with ever-widening effect and, like a rolling snowball, increases progressively. His innumerable activities and their ever-changing facets in the Oxford period are described with arresting skill, and form a suitable memorial, admirably illustrated by successful photographs, of a wonderful personality, the like of whom we shall not look upon again.

HUMPHRY ROLLESTON.

NOTES ON BOOKS.

THE MEDICAL ASPECTS OF CHEMICAL WARFARE.

Is the future medical officers in every branch of the fighting services will need to be specially trained in the treatment of the effects of poisonous chemicals, and to meet this need in the American Army Lieut.-Colonel E. B. Vedder has written a textbook. *The Medical Aspects of Chemical Warfare*.<sup>2</sup> The use of chemical poisons in modern warfare has created many problems in the solution of which the medical services are particularly interested. The making of these poisons will be left to the fertile minds of chemists, and for protection against their danger we hope we may rely also on the ingenuity of chemists; but medical officers will have to know how the different injuries inflicted by suffocating gases, corroding liquids, and venomous solids can best be treated, and it will be necessary always to obtain the opinion of the medical service whenever any protective appliance adds yet further burden to the back of the already heavily loaded infantryman. Apart from these immediate questions, the outlook which chemical warfare has opened up may call for a reconsideration of the organization of the medical services in time of war in order to cope with the heavy casualties which chemical poisons, especially new ones, are likely to cause.

Dr. Vedder has treated this important question in a thorough manner. The seventeen chapters of his book can be divided into three sections, dealing successively first with questions of physics, chemistry, and meteorology which govern the use of chemicals in warfare; secondly, with the different agents which may be employed, such as pulmonary irritants, vesicants, lacrymators, irritant smokes, and miscellaneous gases; thirdly, with individual and collective protection against chemical poisons and the treatment of the injuries. A chapter on the naval medical aspects of chemical warfare has been contributed by Lieutenant-Commander WATSON.

The book is based on the experience gained by armies in the late war, and the author acknowledges his indebtedness to Volume II of the *Official History of the War* (London, 1923), which includes a section on the medical aspects of gas warfare; from this British record he often quotes. French and German writings have been consulted also, but these are not quoted so frequently. The American Chemical Warfare School at Edgewood Arsenal became equipped as an important experimental station during the last year or so of the war, and the account of the book, especially there adds greatly to the usefulness of the book, such as because Dr. Vedder describes some new poisons, such as lewisite, which were tested there in 1918, but never actually used in warfare.

It would be reassuring to civilians and soldiers alike to believe that the catalogue of poisons this book describes so carefully included all the noxious vapours, gases, solids, and liquids with which we are likely to be threatened, but, unfortunately, reading the book does not set at rest that uneasy feeling that even worse are to come. At the close of the war rumour was insistent that both sides were about to launch new poisons against which no protection had been discovered. The secret of these is not revealed in this book, but even if they did not exist in 1918 it is quite likely that in the future our chemists, or those of the other side, will invent some such deadly agents. In the meantime, however, Dr. Vedder's book is sufficiently up to date and will provide the military or naval medical officer with plenty to think about.

The three hundred excellent illustrations add greatly to the value of this book.

THE MEDICAL ANNUAL, 1925.

The *Medical Annual* for 1925<sup>3</sup> is the forty-third consecutive yearly issue of this popular book. It takes the same form as its immediate predecessors, and aims, like them, at giving a general review of the year's work in the treatment of disease. Some thirty contributors, British and American, have written for this volume, each on subjects which they have made their own.

No very dramatic advance in medical knowledge marked the period covered by the present review: it was a time of consolidation and minor excursions. Yet, although we have no obvious argument for claiming greater knowledge than dwellers in 1923, we look upon many questions from a slightly different point of view, than before. So the cards are shuffled, and every year a different hand is dealt to the readers of the *Annual*, whose 500 pages represent the opinions of the day. We do not mean to suggest by this that there is little fresh in the new volume—that it is Sunday's dinner warmed up again for Monday; on the contrary, an amazing quantity of new scientific information is presented. We might have wished that elements of this had been sifted more critically, or at any rate accompanied by some comment, and we wonder how often, if a new edition were demanded in 1935, the editor's blue pencil would erase sentences which stand facing us now unchallenged.

The introduction of each subject in the body of the book, the fuller exposition of each subject in the provinces where doctors are changing are well guided to what is new and trines are changing are well guided to what is new and promising. Other readers, aiming direct at some special question, will have no difficulty in finding their way to what they want, because the book is excellently indexed, the more important articles being in heavy type. The forty-three plates, and more modest line illustrations (149 of them) serve a useful purpose in explaining the text. For the benefit of any who may not be acquainted with the general construction of this hardy annual we may add that purchasers are presented with a lot of other information in this book beyond that contained in the dictionary of practical medicine. Thus we are told about hydropathic establishments, principal British spas, and many other things. The *Medical Annual* for 1925 is an excellent investment, and the only regret which purchasers will experience will be that they did not order it before April 7th, when they might have had it for three shillings less.

NOTES ON BOOKS.

THE first edition of Dr. PERCY HALL'S book *Ultra-Violet Rays in the Treatment and Cure of Disease* (reviewed in this JOURNAL, February 28th, 1925, p. 413) has been quickly followed by a second.<sup>4</sup> Apart from a few minor alterations and the addition of a chapter on smokeless fuel, very little change has been made in the book, which remains a clear exposition of the manner of employment of natural and artificial light in the treatment of disease. If the medical profession needs more guidance in the use of these greater popular remedies, the general public stands in even greater need of more accurate knowledge concerning heliotherapy and ultra-violet ray treatment. As Dr. Hall points out in the preface to his second edition, the "violet ray" apparatus which hairdressers and others are pressing upon a miniature of their customers is likely to bring ultra-violet ray therapy into discredit. The "violet ray" apparatus is a miniature high-frequency machine and cannot be looked upon as a suitable appliance for the treatment of conditions of ill health and disease amenable only to ultra-violet radiation. A danger threatens the whole science of light therapy because of its rapid rise to the notice of the public. This new method of treatment should only be administered by those who have had a proper course of instruction in its application. There are signs that unqualified persons are making ready to exploit for their profit this promising line of treatment, which, as has been abundantly proved, can only be of value when accurately employed by skilled workers.

A work which has gone through ten editions since the beginning of the present century has evidently found a public. Dr. RAKHAL DAS GHOSH, a Calcutta physician, produced a *Treatise on Materia Medica and Therapeutics*, but died while the first edition was passing through the press. The second volume of the first edition and the next two editions were

<sup>2</sup> *The Medical Aspects of Chemical Warfare*. By E. B. Vedder. With a chapter on the Naval Aspects of Chemical Warfare by D. C. Walton. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox, 1925. (Demy 8vo, pp. xvi + 327; 34 plates. 32s. 6d. net.)  
<sup>3</sup> *The Medical Annual*. Fortieth year. Bristol: J. Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. 1925. (Demy 8vo, pp. xvi + 608; 149 figures, 43 plates. 20s.)  
<sup>4</sup> *Ultra-Violet Rays in the Treatment and Cure of Disease*. By Percy Hall, M.R.C.S. Eng., L.R.C.P. Lond. Introduction by Sir Henry Gauvain, M.A., M.D., M.C.C. Camb., and Leonard E. Hill, M.B. Lond., F.R.S. Second edition. London: W. Heinemann (Medical Books), Ltd. 1925. (Demy 8vo, pp. xx + 114; 9 plates. 7s. 6d. net.)

edited by Lieut.-Colonel C. P. Lukis, the fourth by Lieut.-Colonel J. T. Calvert, the fifth by Lieut.-Colonel B. H. Deare. These three officers successively held the appointment of Principal and Professor of Medicine in the Calcutta Medical College. The next four issues were edited conjointly by Deare and Dr. B. N. Ghosh, the son of the author. The new edition<sup>5</sup> is due to Dr. B. N. GHOSH alone. The whole text has been revised and the most recent works on pharmacology have been drawn on for the latest views on now drugs. Several drugs of minor importance, now little used, have been omitted; insulin appears for the first time and a couple of pages on vitamins have been added. The work is well adapted for a student's manual, as well as for handy reference by men in practice.

Volume xlv of the *Transactions of the Edinburgh Obstetrical Society*<sup>6</sup> for the session 1923-24 has been issued. Amongst the communications relating to obstetrics, which forms the first part of the volume, are papers by Dr. S. J. Cameron and Dr. Farquhar Murray on Caesarean section; observations on seventy years of country midwifery practice, by Dr. C. E. Douglas; and a paper on the induction of labour by quinine and pituitrin, by Dr. F. J. Browne, who contributes also an article on stillbirth and neo-natal death, in continuation of his previous publications. The communications relating to gynaecology contain contributions from Drs. Haig Ferguson, R. W. Johnstone, and James Young. The eloquent valedictory address by Dr. Lamond Laekie on recent advances in obstetrics and gynaecology occupies the first twenty-five pages of the volume.

We have recently received the third edition of the second volume of Dr. R. C. CABOT's work on *Differential Diagnosis*<sup>7</sup>; the first edition of it was noticed some ten years ago (*JOURNAL*, July 24th, 1915, p. 141). The volume consists of nineteen chapters devoted respectively to the consideration of the following heterogeneous subjects: abdominal and other tumours, vertigo, diarrhoea, dyspepsia, haematemesis, glands, melaena, swelling of the face, haemoptysis, oedema of the legs, frequent micturition and polyuria, fainting, hoarseness, pallor, swelling of the arm, delirium, palpitation and arrhythmia, tremor, and ascites and abdominal enlargement. Each chapter commences with general considerations, which are followed by a detailed description of individual cases, of which the volume contains 317. As was pointed out in our notice of the first edition, some doubt may be felt as to the utility of such a method, as in comparatively few cases was the opportunity of a necropsy or satisfactory biopsy afforded, so that the diagnosis of the great majority was open to question.

<sup>5</sup> *A Treatise on Materia Medica and Therapeutics, including Pharmacy, Dispensing, Pharmacology, and Administration of Drugs.* By the late Rakhil Das Ghosh. Tenth edition, by Barendra Nath Ghosh, F.R.F.P. and S.Glasg. Calcutta: Hilton and Co.; London: H. K. Lewis and Co., Ltd. 1925. (Cr. 8vo, pp. xii + 718. 10s. 6d. net.)

<sup>6</sup> *Transactions of the Edinburgh Obstetrical Society. Session 1923-24.* Vol. xlv. Edinburgh: Oliver and Boyd. 1924. (Med. 8vo, pp. xix + 231; illustrated.)

<sup>7</sup> *Differential Diagnosis.* Vol. II. By R. C. Cabot, M.D. Third edition. Philadelphia and London: W. B. Saunders Company. 1924. (Roy. 8vo, pp. 703; 254 figures. 42s. net.)

## ROYAL SOCIETY OF MEDICINE.

### THE RETIREMENT OF SIR JOHN MACALISTER.

EVERY Fellow of the Royal Society of Medicine will have learnt with keen regret from the announcement we made last week that ill health has compelled Sir John MacAlister to resign the office of secretary, which he has so long, so honourably, and so devotedly filled. At the meeting of the Council of the Society last week the following resolutions were proposed from the chair:

1. That the Council of the Royal Society of Medicine desires to express its profound regret that ill health has compelled Sir John MacAlister to resign his office of secretary, which he has held since the year 1887. In accepting his resignation the members fully realize that the Society as at present constituted owes its creation to his organizing powers; that its growth and success are chiefly due to his zealous devotion to his duties; and that its welfare and reputation have been his life's work.
2. That the Council unanimously offers its most sincere thanks to Sir John MacAlister for his thirty-eight years of ungrudging and loyal service to the Society.
3. That the Council sends its affectionate good wishes for Sir John MacAlister's restoration to health and vigour.

4. That the Council has great pleasure in inviting the Society to elect Sir John MacAlister as an Honorary Fellow of the Society.

In submitting these the President, Sir STCLAIR THOMSON, reminded the Council that their permanent secretary had been overcome with illness and absent from the Society's house since December 16th. On January 20th he had been granted three months' leave of absence, and during his absence a great deal of the administrative work had been willingly and admirably carried on by Mr. W. Girling Ball, one of the honorary secretaries. The President said he felt sure that the letter of resignation must have caused the writer a sorrowful pang, for Sir John had devoted his life to the Society, and all his work, his joy, and his satisfaction of life had concentrated in its service. The profession had been fortunate in finding in MacAlister the one man able to effect an amalgamation which, though often attempted, had baffled others for a hundred years. He recalled the three great and successful achievements of Sir John's life-work. The first was the move of the old Medico-Chirurgical Society from Berners Street to a building in Hanover Square, large enough to house it, to lodge its increasing library, and to supply meeting rooms to many kindred societies. The second was the federation of these eighteen societies into the Royal Society of Medicine, the largest society of its kind in the kingdom and with the most complete medical library in the empire. The third great feat was the erection of the Society's handsome house in Wimpole Street, the move there, and the consolidation of its success in numbers, meetings, published Proceedings, wealth, and general prosperity. He felt sure that no formal resolution could be too generous in making public acknowledgement of the indebtedness and affection the Society felt towards Sir John MacAlister and the deep regret all experienced on realizing that his health prevented him from continuing his duties.

Two previous Presidents of the Society, Sir HUMPHRY ROLLESTON and Sir WILLIAM HALE-WHITE, took occasion, in supporting the resolutions, to refer to MacAlister's devoted work during their years of office. Sir Humphry recalled the small beginnings he remembered in Berners Street, and the constant, loyal, and single-hearted service of their secretary. Sir William referred to the personal touch, the friendliness, the accessibility of MacAlister, and his eagerness to help anyone—whether a Fellow of the Society or not—and in any way, even if unconnected with the Society's work.

The resolutions and the terms in which they were commended by the President of the Royal Society of Medicine and two of his predecessors will be warmly and heartily approved by all who have come into contact with Sir John MacAlister, whether officially or socially, and by none with more conviction than those who remember his achievement in bringing about the amalgamation in 1907 of the eighteen societies which then existed in London. His was not the first attempt to achieve the desired result; the fact that other attempts had failed, including one under very favourable auspices only a few years before, is a proof of the difficulty of the task and of the high qualities MacAlister brought to bear on its final solution. MacAlister was devoted to the interests of the Society which he had done so much to bring into existence, to consolidate, and to render one of the great medical organizations in this country. He was also ever ready to assist in any enterprise which he believed was for the good of the profession, and we may especially mention his large share in establishing the Fellowship of Medicine and organizing at Christmas, 1918, the post-graduate courses in London, which, during the first half of the following year, met the needs of a large number of medical officers then being demobilized, including those of the Australian, New Zealand, and Canadian armies. It is only consistent with his high sense of duty that he should have resigned his office solely on the ground that he felt that he has not now the vigour necessary for the adequate performance of its many duties. His resignation does not take effect until the end of June. We hope that until then, and long afterwards, he will continue to come among his many friends in the profession on every social occasion.

SATURDAY, MAY 2ND, 1925.

## CHEMICAL WARFARE.

THE use of poisonous gases and other chemicals in warfare, though denounced by the Washington conference on the limitation of armaments, remains a controversial issue and a disquieting theme for speculation. Many powerful nations were not represented at that conference, and have not signified their intention with regard to poisonous chemicals; but even if all were to join in the chorus of disapproval it would be wise to remember that gentlemanly rules for warfare are quickly set aside in a life-and-death struggle. At the present moment probably every well armed "civilized" nation is asking its chemists—or watching its neighbours—to find a poisonous gas or liquid which would put enemy forces quickly out of action, and no doubt also scientists are being asked by their respective Governments how soldiers and civilians can best be protected against deadly or crippling chemicals to which they may suddenly be exposed. In times of peace the civilian population, of this country at least, is not much interested in the technicalities of warfare, and leaves such questions to experts; but many people who would leave the choice of their shrapnel to soldiers or their warships to sailors feel that they would like to be made acquainted with what is being done about poisonous gases—partly, perhaps, because they know that in time of war everyone, civilian and soldier alike, will have a personal interest in the question. It is a good thing, therefore, that the subject of chemical warfare should be studied in a scientific way and expounded in a reliable textbook which anybody may read—such a book, for instance, as that by Lieut.-Colonel Vedder, reviewed at page 845.

To form a sound judgement on the question of the use of gas in warfare we must realize that it is certain to be employed. It is probably on this account—because it is believed that there are nations which will not hesitate to use poisonous gases and the like against civilian populations, including their children and women—that opinion has revolted against the method. There are those who think that wars may in this way be brought to an end, and we can only hope that they may be right. However this may be, it will not be wise to denounce chemical warfare as a nasty modern innovation into the respectable and time-honoured custom of killing our fellow men with bayonet and shot. This opinion, its nakedness decently cloaked, is sometimes upheld by the professional soldier, but it has to be admitted that all new weapons, including gunpowder, shrapnel, and machine guns, when first introduced were denounced as infringements of the rules of the game, yet their employment is now considered to be perfectly compatible with "sportsman-ship." There remains, however, one objection to chemical warfare which is deep-rooted in the minds of many people, and about which medical men ought to give some guidance—namely, that chemical warfare is more barbarous, more cruel, more merciless than other weapons of warfare. What truth is there in this?

Mr. J. B. S. Haldane, reader in biochemistry at Cambridge University, vigorously defends chemical warfare in an entertaining little essay called *Callinicus*;

it forms one of a series, the first of which—*Dædalus*, by the same author—was an amusing forecast of the future of science, which probably many of our readers have enjoyed. The title of the present essay commemorates the exploit of a Syrian architect, Callinicus, who in the seventh century fled from Heliopolis to Constantinople with the secret of the "Greek fire," a chemical substance which, when thrown out from siphons, set the ships of the Saracens on fire and assured their defeat. The title of this essay, as also the historical chapter in Dr. Vedder's book on chemical warfare, serves to remind us that the use of noxious chemicals in war has at least the sanction of a precedent that dates from before April 22nd, 1915.

Mr. Haldane states that the twenty-five poisonous chemical weapons employed in the late war can be divided into four classes according to their effect on men. First come gases and vapours which are poisonous when inhaled but have no effect on the skin, and affect the eyes or nose only when present in concentrations which are poisonous to the lungs. This group, which includes chlorine and phosgene, can all be kept out by respirators; they are of military value only against unprotected troops, and, he believes, "almost as obsolete as muzzle-loading cannon." The members of the second group only irritate the eyes, and there is no evidence that anyone was killed or permanently blinded by these substances. They cause men to weep profusely, but can be kept out by respirators or even goggles. A third group of poisonous smokes, mostly arsenic compounds, were very little developed during the war, but would probably have been used on an extensive scale in 1919. The fourth group, of blistering liquids, includes the very powerful irritant "mustard gas," which produced more casualties to the British than all other chemical weapons put together. Mustard gas caused 150,000 casualties in the British Army alone; under 4,000 (or 1 in 40) died, while about 700 (or 1 in every 200) were rendered permanently unfit. The signatory powers of the Washington conference have agreed not to use this substance against one another, but in the heat of war they may forget. It is therefore some consolation to be told that it would appear to be one of the least lethal of available methods of putting an enemy out of action.

Mr. Haldane's defence of chemical warfare, and also Dr. Vedder's more substantial book, both support the view that in the late war poisonous chemicals were less cruel weapons of warfare than bombs, shells, and bullets; but it is at least conceivable that in a future war chemists may provide us (or our enemies) with some much more powerful poison. Such a compound is most likely to be found among the poisonous smokes; in fact, there is a substance called lewisite—so named after Professor Lewis, who first isolated and described it in 1918—which, because of its highly irritating and poisonous properties, would certainly have been used by the British and Americans had the war gone on a little longer. In small amount these smokes make a man sneeze; in larger quantities they cause agonizing headache and uncontrollable distress. Mr. Haldane says: "Some soldiers poisoned by these substances had to be prevented from committing suicide; others temporarily went raving mad and tried to burrow into the ground to escape from imaginary pursuers." Yet in spite of this acute misery the large majority had recovered within forty-eight hours, and practically none became permanent invalids. Used in the form of smoke, these substances will penetrate any of the respirators used in the late war, though the British box respirator offers a considerable degree of protection.

There is a good description of lewisite, and also of some other chemical poisons which the Allies were preparing, in Dr. Vedder's volume, which is intended to serve as a textbook for medical officers in the services; but *Callinicus*, which can be read from cover to cover in about fifty minutes, is of universal interest.

### OYSTERS AND MAYORAL BANQUETS.

In the year 1902 a mayoral banquet at Winchester resulted in serious illness among those who took part in it. Out of 134 guests 62 were subsequently taken ill; 9 of these developed typhoid fever, and 4 died. The cause of the illnesses was, on investigation, found to be the consumption of oysters. In the same year Southampton had a similar unfortunate experience. There also a mayoral banquet took place, and of 132 guests 55 fell ill, 11 of them with typhoid fever. One of the 11 died. Oysters were again found to be the vehicle of infection.

These facts are recalled by Dr. Mearns Fraser in a report of an outbreak of similar illness among the guests at a mayoral banquet in Portsmouth. The total number of persons partaking of the meal was 135, and 83 of them suffered some illness within a few days. The symptoms were those of acute gastro-enteritis, and three of the patients developed definite paratyphoid fever of severe type, though no death occurred. Once more, as shown in Dr. Mearns Fraser's clear and concise report, oysters were proved, by a process of exclusion, to have been responsible for the outbreak. Adopting the method of investigation used by the late Dr. Timbrell Bulstrode of the Local Government Board, as recorded in his classical reports on the subject of oyster contamination, Dr. Fraser communicated with all those who had partaken of the viands provided, and obtained from each a statement showing every item he had consumed of the seventeen contained in the menu. Of the 83 who became ill 82 had had oysters and 81 had had soup; these were the only articles under real suspicion, pheasant and salad, coffee, and lamb cutlets, which came next in order of frequency, being practically out of the question. It may be assumed that the salad was exculpated, though "greencstuff" is not unknown as subject to contamination. Inquiry regarding the soup showed that the stock had been repeatedly boiled, and that the soup itself had been brought to the boiling point shortly before the dinner was served.

The facts regarding the three persons who developed paratyphoid fever are interesting. The date of the banquet was November 10th; two days later one of the three had an attack of vomiting, and continued to feel somewhat indisposed until November 27th (seventeen days after the dinner). When he was medically examined he had a temperature of 104° F., and was found to be suffering from paratyphoid B. Another of the three felt no ill effects until November 28th, when his temperature was found to be 105° F., and a blood test later showed paratyphoid B bacilli. The illness of the third began four days after the dinner and continued until November 26th, when he took to bed and was found to be suffering from paratyphoid B. All three thus developed the definite symptoms of specific infection about the same time, sixteen to eighteen days after the dinner. Questions suggest themselves as to the relation between the general bacterial contamination of the oysters and the pathogenic bacillus, but these cannot be entered on here.

Dr. Fraser ascertained that 412 oysters had been

supplied for the occasion. Incidentally, excessive indulgence in them could not be held responsible, for the number served to each guest was only three; and this was the case at each of the two banquets in 1902. Indeed, at Winchester a guest who swallowed only one oyster died from typhoid. The oysters for the Portsmouth dinner had been dredged from beds at two places in the Solent—one near the Warner lightship, and the other the Boyne Bank, about half a mile off Southsea Castle. None of those actually provided for the occasion were, of course, available for examination, but Dr. Fraser had dredgings made at both places, and at his request the Fishmongers' Company had the oysters so obtained examined by Professor Eyre of Guy's Hospital, bacteriologist to the Company. Of ten oysters from the Warner Bank, one contained the *Bacillus coli*, the other nine were clean; of the same number from the Boyne Bank no fewer than six showed the *Bacillus coli*, and one the *Bacillus enteritidis sporogenes*. Such oysters are, according to present standards, to be regarded as unfit for consumption, and would not be allowed on the London markets, but the one-in-ten contamination from the Warner Bank dredging would not exclude them from sale in London.

Dr. Mearns Fraser points out that under the law as it stands at present there is no obstacle to the sale in Portsmouth of oysters dredged in its neighbourhood, with the single exception of those from Langston Harbour, from which, under regulations made in 1918, oysters must not be sold unless they have been relaid at certain other layings; the enforcement of this regulation must manifestly be difficult. He holds that protection, indeed, lies with the individual, the only safety of the public being to see that they obtain oysters from firms guaranteeing that their layings are under inspection and approved by a competent authority. It appears that for retail shops perfectly safe sources are available under action taken by the Fishmongers' Company, which keeps most of the principal layings in the country under constant observation, so that they are maintained in a state of purity. As Dr. Fraser urges, oyster beds cannot be defended merely because they may for long periods be used without any proof of having caused disease. Sewage will vary from time to time in concentration and in bacterial content. Tidal influences also are at work. The greatly diminished prevalence of typhoid fever throughout the country manifestly lessens risks of infection of oysters by specifically polluted sewage, but the Portsmouth banquet demonstrates that the possibility remains, and from the preventive side the position should be once more reviewed. It may be safely assumed that the Ministry of Health will give due attention to Dr. Fraser's report, and to the question which it raises as to the value of the regulations commented on therein. The situation is at present frankly unsatisfactory.

### THE BUDGET.

If the framing of the Budget had fallen this year to the lot of a Minister with a reputation for caution to maintain, it would probably have evoked less interest than is usually the case. By this time the average taxpayer entertains little hope of receiving substantial relief through reparation payments or by the repayment of loans made to other countries. He realizes that there is no easy or immediate escape from the

MAY 2, 1925]

# THE BUDGET.

THE BRITISH  
MEDICAL JOURNAL. 849

burden of high taxation, and that its deadening weight will only be reduced gradually, and, in the main, by his own efforts. Nevertheless, Mr. Churchill's well founded reputation for energy and freshness of mind created a general expectation, or at least a hope, that he might achieve some ingenious and drastic handling of the problem which would provide real and immediate relief without offence to the canons of sound finance. It does not often happen that widely read organs of the daily press are found to be discussing the possibilities of a shilling reduction in the rate of income tax while more sober weekly journals—such as the *Economist*—are pointing out that, on the known facts of the case, a reduction of sixpence would hardly seem feasible without increased taxation in some other direction. An examination of Mr. Churchill's speech suggests that once again the wish has been father to the thought.

A striking feature of the figures for the past fiscal year is the narrow margin between income and expenditure. The day of swollen surpluses has passed, and there is good ground for regarding their passing without regret. It is true that past surpluses have played a large part in the unprecedented reduction of the National Debt, but to a large extent these surpluses were obtained in years during which assets of various kinds, which had been acquired with borrowed money for war purposes, were being realized and the proceeds dealt with as public revenue. Now that the source of such receipts has dried up taxpayers have a large ground of complaint if, after providing for a large repayment of debt—the amount will be £50,000,000 in the present year—they found that the taxation they had been called upon to bear had provided for a sum substantially greater than, after due consideration, was considered appropriate. Especially is this the case in view of the fact that the annual charge in respect of war pensions shows, and presumably will continue to show, a steady decrease.

In commenting on the accuracy of his predecessor's forecast of a surplus of £4,000,000 for the past year, Mr. Churchill paid him a handsome compliment on his financial administration, with the qualification that the figures for individual items showed that "Mr. Snowden had been fortunate as well as far-sighted." Even allowing for the steady effect of the three years' average system of the income-tax assessments, the Exchequer receipts are affected by comparatively small variations to an extent that is realized by most important people. Consequently one of the most important duties of a Chancellor is his preliminary survey to ascertain the trend of trade generally, and at the present time, when signs of recovery from depression are eagerly sought for, Mr. Churchill's pronouncement on this question was plainly given, and is not particularly encouraging. "I do not feel justified," he said, "in budgeting for any substantial expansion of trade." Nothing is gained by a refusal to face facts, and though this sober statement may damp the ardour of those who wish to "talk up" a trade revival, its modified optimism should prove helpful.

With no trade boom on the horizon to increase the receipts, with departmental estimates of expenditure still increasing, and an additional five millions to provide for debt redemption—an increase necessary to carry out the programme outlined by the present Prime Minister when Chancellor—any drastic reduction in taxation becomes impossible without recourse to some scheme, such as the funding of war pensions, which would postpone expenditure to future years. On the contrary, Mr. Churchill is taking care to maintain the

income of the Exchequer by new or increased taxation in various directions. The death duty rates are to be increased on estates of £12,500 and upwards, and other duties are imposed which seem to have a twofold basis—they affect luxuries and are aimed at stimulating home industries. Into this category fall the duties on silk, on hops, and the group of duties—on motor cars, musical instruments, watches, etc.—commonly known as the McKenna duties. Beyond this, the receipt of £9,500,000 is anticipated from reparations, but the Budget does not take into account the prospect of any repayment by France of money lent to her. New taxation does not fructify quickly, and the receipts anticipated from these changes are, in round figures, ten millions in the present year and twenty millions next year. Taking into account Mr. Churchill's statement that a fresh attempt will be made by the Treasury to cut down expenditure, it is clear that he is looking to the future for that substantial reduction in taxation which, in some quarters, was hoped for this year. His proposals, however, enable him to show a surplus—on the basis that the present taxation remains and is augmented by the suggested changes—of £37,000,000, and on that basis he has material on which to draw for some relief to the hard-pressed taxpayer. Of this amount the additional receipts from estate duties are returned to the same class of the community in the form of a reduction in the rates of supertax applicable more especially to total incomes in the lower categories liable to that tax. This transfer of taxation from income to capital, and from the less wealthy to the very wealthy, has already aroused some criticism, but the basic idea seems sound—that is, to avoid excessive pressure on the brain worker, whose income ceases after his ability to perform difficult tasks has been lost.

The income-tax proposals are particularly interesting. The increase in the allowance for earned incomes will afford substantial relief to taxpayers with earned incomes below the supertax limit, and particularly to those under £1,000. By this alteration the Chancellor reverts to the larger relief for earned incomes which was reduced when the method of computing it was changed by the Finance Act of 1920. A small but welcome addition is made to put the income from savings of old people with total incomes not exceeding £500 per annum in a similar position, even though no portion of their income is then being earned. Lastly, the anticipated reduction of sixpence in the standard rate is made, so that income from investments may benefit, though not so substantially as earned income.

Budget statements, though never devoid of interest, are usually confined to purely fiscal questions—estimates of future or statements of past receipt and expenditure. This year the Chancellor discussed two other related topics—the question of the "gold standard" and the launching of a comprehensive scheme of contributory insurance. Of the former it must suffice here to say that the prohibition of the export of gold will be withdrawn subject to supervision by the Bank of England, that precautionary measures have been taken to prevent difficulties being met with in the repayments of loan to the United States, and that a link will be maintained between the price of gold and the purchasing power of the currency notes, though the issue of gold coinage is not proposed. It would be premature to enter into a discussion of the new insurance scheme; comment thereon must await an examination of the details of the proposal. On the face of it the scheme seems to constitute a long step forward on lines likely to commend themselves to the

country generally. Assuming that all the political parties address themselves to the task of developing the ideas put forward into a practical and businesslike scheme, this Budget may prove a landmark in the progress toward the emancipation of the poorer classes of the community from the anxieties at present attendant upon inability to provide for their own support in old age, or that of their dependants in the case of premature death.

Mr. Churchill has justified his reputation for ability to handle large problems with imagination and sound knowledge. He is providing for a great extension of one of our most important social schemes, and has, we believe, applied a not inconsiderable instalment of income-tax relief to the class of taxpayer most deserving of sympathy—the man who, without resources in the form of invested capital, is struggling to earn an income sufficient to provide for his dependants and himself, and at the same time to make adequate provision for their support after his retirement or death. Certainly most of our readers appear to have cause to thank him for his efforts.

#### THE SURGEON'S RESPONSIBILITY.

Discussions such as that evoked by Lord Riddell's paper upon "The legal responsibility of the surgeon" before the Medico-Legal Society (of which an account appears at page 842) serve an important educative purpose to the medical profession. If only to protect themselves from such pitfalls beset the path of the medical man in pursuing his life work, members of the medical profession would do well to instruct themselves fully as to their legal responsibilities, both civil and criminal. For it may be that in their very real anxiety to keep within the law they may refuse to relieve a case which it would be both humane and lawful for them to relieve. Professor Louiso McIlroy cited such a case in the course of the discussion. It was one of a working woman with an ovarian tumour which caused her great pain, but her husband, in consequence of a quarrel they had had, would not consent to the removal of the tumour, and so the woman left the hospital unrelieved. Professor McIlroy did not think the problem whether such an operation should be performed in such circumstances would ever be cleared up; but Lord Riddell, in his paper, had already expressed the legal view that, while the husband might well have a cause of action against his wife and the surgeon for depriving him of the possibility of offspring, it seemed clear that the husband would have no claim in respect of such an operation when rendered necessary by definite pathological conditions. In these days, added Lord Riddell, a wife could not be condemned to submit to illness, and perhaps to risk of life, because her husband declined to consent to a surgical operation. Lord Justice Atkin, the learned president of the society, said that he knew of no rule of law which compelled the surgeon who was called in by a wife to obtain the consent of the husband to the treatment which he should adopt. True, if the surgeon was looking to the husband to pay his fee he should have the consent of the husband, being the person who had promised to pay such fee; but apart from that, and any question of wrong or tort (by which Sir Richard Atkin meant provided the doctor acted *bona fide* and with due skill and care), he imagined that the consent of the woman was sufficient to justify the surgeon in exercising his care and skill upon her. Upon the high authority of Lord Justice Atkin, therefore, a case such as that quoted by Professor McIlroy ought to have been relieved if the wife were a consenting party—as it appears she was—for it obviously was not a case where the husband was being looked to for payment of fees.

#### THE SIGNIFICANCE OF PAPILOEDEMA.

In September, 1924, a symposium on papilloedema was held at the meeting in Montreal of the American Academy of Ophthalmology and Oto-Laryngology. The March issue of the *Archives of Ophthalmology* contains three of the papers then read, setting forth the present views on the significance of this condition held by an ophthalmologist, an oto-laryngologist, and a neurologist. J. Bordley, jun., points out that in the large majority of cases papilloedema is not a local ocular infective lesion, but a mechanical effect of the increased intracranial pressure, and therefore the ophthalmologist should obtain expert advice from specialists in other fields. No time should be lost in doing this, because the longer the morbid process continues the greater in extent will be the final loss of vision. Bordley believes that there is considerable danger of overestimating the frequency of sinus disease as the cause of papilloedema, and that the result is disastrous to the patient's vision. Foci of infection remote from the brain and optic nerve are rarely found to be the cause of choked disc. G. Horrax remarks that statistics indicate that in 80 to 90 per cent. of cases of papilloedema the increased pressure is due to cerebral tumour. He describes five cases in which delay in suspecting a cerebral lesion led to permanent loss of vision in spite of operative treatment that was otherwise successful. L. E. White, speaking from the oto-laryngological standpoint, insists that a very careful study of the neurological side of the case should precede any intranasal operation for the possible presence of accessory sinus disease. He draws attention in particular to unilateral inflammation of the optic nerve directly traceable to an infected nasal sinus. This condition of papillitis is clinically distinguishable from true papilloedema in that it is unilateral, and vision is lost from the first, in contradistinction to papilloedema, where the vision is affected late and the swelling of the disc does not usually become so extreme. Although vision in papilloedema is often not affected until some time after the onset, it is not desirable to allow the disease to continue, since secondary atrophy of the nerve may result from pathological changes which increase proportionately to the length of time and severity of the papilloedema. White concludes that the rhinologist should restrict his surgical treatment to these acute unilateral cases, and so avoid the risk of opening an accessory sinus unnecessarily. These sinuses, he is convinced, should be left alone unless they present evidence of infection.

#### FISH AND MOSQUITO CONTROL.

MALARIA is one of the most widespread and serious diseases in the world, and for that reason has been selected by the International Health Board of the Rockefeller Foundation for concerted action. There are several main lines of attack, and among them one of the most important is an attack on the mosquito. This has been attempted on a large scale by the use of oil and poisons in the breeding sites, by drainage, and so on. Another method, which has frequently been recommended as a supplementary measure, is the use of larviferous fish. So far it has not been attended by much success, but the International Health Board has recently published a report on it.<sup>1</sup> The principle of biological control, as this method may be called, has been used frequently, and often successfully, in agriculture. Any interference with the balance of nature, however, has to be attempted cautiously and only by experts—rabbits in Australia and sparrows in the United States are two examples of man's ill advised handiwork. There is evidence, however, that the use of fish, if carefully supervised, is effective in mosquito eradication. In the report, which is copiously illustrated, it is pointed out that the problem is complex. The species of fish to be chosen depends on the

<sup>1</sup> *The Use of Fish for Mosquito Control*. Pp. 120. 1924

locality and the habits of the particular larva to be attacked. Thus, for example, the larvae of the malaria mosquito are "top-feeders," and so top-feeding fish are necessary. On the other hand, the larvae of the yellow fever mosquito are mainly "bottom-feeders," and so minnows of different feeding habits must be used. The type of breeding place and many other factors vary, and must be separately considered. The report is in the main concerned with a consideration of the fish used in the various parts of the world. It appears that, where fish have been scientifically used, the malarial index has been reduced, that they have been a complete success against yellow fever, and that "within limits, perhaps not so narrow, as may be supposed, this method is ready to take its place as a recognized ancillary means of both yellow fever and malaria mosquito control." The usefulness of the report is greatly increased by a comprehensive bibliography.

#### PLAGUE IN SOUTH AFRICA.

For some years past the existence of plague in South Africa has been a cause of anxiety there. The report for the year ended June 30th, 1924, by Dr. J. A. Mitchell, Secretary for Public Health and Chief Health Officer of the Union of South Africa, shows that the anxiety is well founded. During the year there were 167 outbreaks in the Union, causing 372 cases, with 235 deaths. The great majority—321 cases and 208 deaths—were in the coloured and native population; the number of whites attacked was 51, with 27 deaths. About 85 per cent. of the cases were bubonic, 12 per cent. pneumonic, and the remainder septicæmic. Kissing is believed to have been the mode of infection of most of the pneumonic cases. Notwithstanding much publicity, all cases were not promptly reported. This applied to Europeans as well as natives; consequently there was delay in diagnosis and precautionary measures. The main cause for anxiety, however, is the prevalence of the disease among rodents. Plague was introduced to Cape-town and Port Elizabeth in 1901 by infected rats from ships bringing forage from South American ports, where the disease existed at the time. It was introduced to Durban in 1902, and extended to Johannesburg in 1904. Epizootics occurred amongst domestic rodents and concurrent epidemics in man, fleas being, as usual, the intermediary. Wild rodents were found infected in the outskirts of several towns. Since 1912 many outbreaks have been discovered, and in 1923 a survey of wild rodents in the Orange Free State and Cape Midlands revealed plague infection over a wide area. Last winter the epizootic spread extensively in the territory surrounding Bloemfontein, and the area of the Union now known to have enzootic plague infection is about 50,000 square miles. Dr. Mitchell states that in the Kroonstad district and adjoining parts, owing to the recent epizootic, it is estimated that 80 to 90 per cent. of the total veld rodents, and from 30 to 40 per cent. of the associated small carnivora (mongoose and suricates), died of plague. Plague bacilli have not often been found in the carnivores, but they eat enormous numbers of rodents, and may have died from poisoning by toxins; also they may be carriers of fleas from the dead rodents. In some localities in the height of the epizootic dead rodents could be collected by the barrowful. The difficulties under such conditions in the way of controlling the disease are enormous. The South African Biological Society has made strong representations to the four provinces of the Union that the natural enemies of rodents, such as owls and hawks and wild cats, should be protected. The balance of nature has been seriously disturbed by their destruction in many localities, where rodents are a pest apart from plague. Some farmers, indeed, by preserving bush, planting trees, and stopping of veld burning and shooting, have greatly reduced the evil.

One enterprising farmer turned loose a consignment of domestic cats, and by limiting their regular diet of milk led them to hunt for most of their food, and has largely cleared his farm of rodents. Inquiries made early in the epizootic revealed the infestation by rodents dying of plague of a large number of grain stacks on farms and at railway stations, intended for transport or export. Regulations were issued prohibiting such conveyance, and measures were taken to make the regulations effective, with such success that no instance of failure is known, notwithstanding the inconvenience and loss involved in the prohibition. An active campaign was instituted of search for and destruction of rodents, both in railway trucks and in localities. But Dr. Mitchell goes on to say that the problem has hitherto been found almost insoluble in the large tracts of country in South Africa. The gassing of veld rodents in their burrows and in stacks of grain by carbon disulphide is costly and tedious, though hydrocyanic acid is more promising. The dynamiting of rodent burrows is also proving useful. Poisoned baits have been devised with some success. Strips of country are being selected for special effort in the formation of "plague fire belts" designed to limit epizootic extension. But further investigations—zoological, entomological, and bacteriological—are urgently necessary, and proposals to that effect have been submitted to the Government. In a valuable appendix Dr. Mitchell submits a detailed scheme of investigation under each of these three headings, and his proposals, it may surely be assumed, will receive the earnest and sympathetic attention of the South African Government.

#### BILLROTH.

In the last third of the nineteenth century probably no surgeon was held in higher esteem than Billroth. His famous book written in Vienna became known by means of translations all over the English-speaking countries. Senior students were advised to read it, and most young surgeons made themselves familiar with his doctrines. Before going to Vienna Billroth was seven years in Zürich. We now have from the pen of Dr. Arnold Huber a book on his work there.<sup>1</sup> It is written partly to place on record the debt that the Zürich school owes to Billroth, without any attempt to trace his scientific development as one of the pioneers of surgery; but it is mainly designed to show what manner of man he was. The sentiment running through the whole book is disclosed in Dr. Huber's opening sentence: "Billroth was a man to work with whom was to form a friendship which rapidly mellowed into reverence." Of unusual power, both physically and mentally, he yet possessed a striking gentleness of disposition which rendered him singularly attractive in all his personal relations. Billroth is an excellent example of the true genius, as Dr. Johnson has defined it—"a mind of large general powers, accidentally determined to some particular direction." It is probable that he would have been distinguished in any sphere of activity, but in his earliest years his mind exhibited a distinct trend which left no doubt as to his inclinations. Music was his favourite subject, and to it, so far as his mother's incessant protests would allow, he devoted the whole of his energies, to the exclusion of his regular school studies. He lived, however, in a medical atmosphere, which proved sufficiently powerful to determine the direction of his future career. Professor Seifert, his uncle, had great influence with him, as also had Professor Baum, an intimate friend of the family. Moreover, his private tutors, of whom he appears to have had much need in his school studies, happened always to be medical men. On leaving school and matriculating at the University of Greifswald—the nearest university to his native

<sup>1</sup> *Theodor Billroth in Zürich, 1860-1867. Von Dr. Arnold Huber. Zürcher Medizinisch-historische Abhandlungen. Erster Band. Herausgegeben von G. A. Wehrli und H. G. Sigerist. Zürich: Seldwyla. 1924. (Med. 8vo, pp. xiv + 192; 6 plates. Brosch.; Schw. Fr. 8; geb.: Schw. Fr. 10.)*

island of Rügen—he entered as a medical student, but gave up the whole of his first term to the study of music. Professor Baum, however, took him with him to Göttingen, and his medical career was thus definitely fixed. Billroth possessed an extraordinary vitality, and was obsessed with an craving for work. His day's labours began at 5 a.m. with an hour's practice on the violin; from 7 to 8 he held his operative surgery class, from 8 to 9 studied surgical pathology (at this period he was preparing his great textbook, the first edition of which appeared in 1862), at 9 he visited the wards, from 11 to 12 he gave a clinical demonstration; he operated from 12 to 2, at 3 he returned to surgical pathology and microscopical research, occasionally taking minor operations in the course of the afternoon, and at 6 he again met his class. In the evening a break was always made in the day's work—a visit to a friend's house or some festivity at home, for he was a companionable man, and, moreover, a lover of home life. Music, naturally, figured largely in these festivities, and, indeed, seems to run like a thread through his whole life. There is ample evidence, from expert sources, that he was no mere amateur, but an admirable executant and critic. He instituted and himself took part in a string quartette at his own house, and was to some extent a composer. Dr. Huber reproduces an amusing example of Billroth's musical capacity in the shape of a medical prescription set to music in excellent twelve-part counterpoint for instruments. The day's work, however, did not end here. "He worked mostly at night," writes Dr. Meyers, "for then new ideas come most readily for operations and literary work; and he could generally be seen at night at his open window, working far into the night, sometimes till dawn, thinking and smoking his cigar, which could never be too strong." He was a giant in strength, and probably one of the happiest of men, though he liked to represent life as a symphony of major and minor harmonies interwoven. He had his share of life's troubles: the permanent invalidism of his only son was a constant grief, and the death of two of his three young daughters within a few months wellnigh unhinged his mind for a time. "I tell you in secret," he writes to a friend, "I have wept for nights on end, so you may know the depth of my sorrow." When Billroth left Berlin, where he had acted as Langenbeck's first assistant, and took up his post at Zürich, the main concern that occupied his mind was the management of wounds. This subject was, in a sense, forced upon him, for nearly 50 per cent. of his cases were injuries, mostly of a severe kind; septicaemia and pyaemia were rampant, often necessitating closure of the wards, and, as he himself has stated, "our progress here is over heaps of corpses." He held at this period that the healing of wounds is normally an afebrile process, and the occurrence of inflammation in them an accidental complication, due to contamination by minute particulate substances of unknown nature, which adhered to dressings, bedding, the whitewashed walls, the clothes and hands of nurses and surgeons; moreover, he considered it possible that infection was at times conveyed from patient to patient and from wound to wound. In the light of these opinions he very soon detected many glaring defects in the hospital; and reforms in such matters as water supply, drainage, ventilation, the separation of the dead-house from the hospital, the exclusion of the post-mortem porter from the wards, and the frequent cleansing and repainting of the wards were carried out under his supervision. These matters absorbed much of his time and energies, and furnished material for reflection and study in relation to wound infection. His fundamental principle was that the accidental contaminations of wounds were to be combated by absolute cleanliness. In 1864 Billroth had a call to Heidelberg. There was, however, still much to be done at Zürich, and, moreover, there were both the means

and a readiness on the part of the faculty to assist him in his reforms. These were lacking at Heidelberg, and he expresses regret, as a German, that the Swiss university should be able to serve as an example to the Heidelbergers in this respect. Without a free hand for his reforming activities the appointment lacked attractiveness; he declined the offer. By 1867, however, his work at Zürich appears to have gone as far as he could carry it, and the absence of any forward movement there made him think of other spheres of activity. On the death of Professor Sehniß his thoughts turned towards Vienna, and he put himself in communication with the authorities there. "They received my Vienna fancy in a very friendly way," he writes. "I do not think, however, that anyone in Austria has the least notion of reform in any branch; but if I were offered the appointment, of which I see no chance at present, I would accept it, provided they gave me a free hand for reforms." Much to his delight, he obtained the appointment that same year; he was then in his thirty-seventh year, and evidently looked forward with pleasure to a life of renewed activity, for, writing from his new post to an old friend in Zürich, he says, "None of my colleagues here are under 55, and most are over 60. I am the only baby among them, and I take full advantage of this quaint role; I am beginning to be a veritable *enfant terrible* for them. I boast of Zürich, and tell them what a wretched place this is in comparison." Thus he found himself again in congenial surroundings, and, moreover, in the metropolis of the musical world. At this point Dr. Huber closes his narrative.

#### THE LONDON FIRE BRIGADE.

WITH the intention of familiarizing the great mass of Londoners with its beneficent activities, the London County Council is publishing a number of booklets at low prices. The latest of these sets forth in an attractive manner the history, and describes the work, of the London Fire Brigade.<sup>1</sup> The brigade was created by the Metropolitan Fire Brigade Act of 1865 out of the fire establishment previously maintained by the insurance companies, the organization supported by the Society for the Protection of Life from Fire, and the ancient parochial arrangements—such as they were. There are, we believe, much burdened, but no doubt misguided, ratepayers who think that some of the Council's activities are misdirected and its expenditure lavish and unremunerative; but we cannot conceive of one of those persons evilwilling at the maintenance of the Fire Brigade or grudging one penny of the money spent upon it. Its record is a brilliant one, for its officers and men have for sixty years offered splendid examples of efficiency and gallant devotion to duty. During the war we necessarily heard little of the work of the brigade. All that we knew was that, despite twenty-five air raids, in which 922 bombs were dropped upon London, no fire was allowed to reach unmanageable proportions. We note that all men of the brigade go through a training in first aid, and that provision is made for the treatment of various casualties likely to be met with at fires, but we do not find any mention of any medical officer as in charge of such training and treatment. This booklet contains a most interesting account of notable recent events up to November last, including the Silvertown explosion and the air raids during the war. It seems to us admirably fitted to serve the purpose for which it has been published. It is fully illustrated, and contains a key map and hints on fire protection. We note that a booklet on public health is in active preparation, which should be of even greater medical interest than this one.

<sup>1</sup> The London County Council and what it does for London. *The London Fire Brigade*. With a foreword by Sir James Bird, Clerk of the Council. London: Hodder and Stoughton, 1925. (Demy 8vo, pp. 52; illustrated. 6d. net.)

## Oba et Vetera.

### AN EIGHTEENTH CENTURY PRACTITIONER:

DR. ALBAN THOMAS.

Few physicians nowadays would risk their reputations by giving diagnoses or prognoses of cases merely on a written or viva voce history and without seeing the patient; but for very many years, when travelling was tedious, difficult, and even dangerous, such methods of consultation were much in vogue. Certain taverns and coffee-houses were the resort of medical and surgical consultants, where on fixed days and at regular hours they could be found by apothecaries and surgeons who desired their advice. One of the best known of these places in the eighteenth century was Batson's in Cornhill, frequented by Mead, Blackmore, and others, and later by Sir William Blizard, surgeon to the London Hospital, who died aged 92 in 1835, and is said to have been the last to hold such consultations.

In the Sloane MSS. (4077) there are two letters from Dr. Alban Thomas of Cardigan to Sir Hans Sloane, giving the history of two cases and asking for advice as to treatment. For copies of these we are indebted to Dr. Alban Evans of Swansea.

One of the letters, dated "Wennalt, Novr. 30th, 1738," gives an account of the troubles of Thomas Knolles of that place, in the county of Pembroke, who suffered from obesity (weight 20 stone) and hydrocele, which latter was treated by free incision and was cured in "five or six weeks' time without any mortification which but too frequently happens in such cases." A worse malady for which Thomas sought the advice of Sir Hans was stone in the bladder, from which Knolles had evidently suffered for some years. Sir Hans sent a prescription, but no one seems to have entertained the idea of operation, which alone could have offered a prospect of relief.

The second letter runs as follows:

Most Honble Sir,

I have presumed upon the foot of former Acquaintance with your honr to recommend the Case of this Revd & worthy Gentleman to your perusal, well knowing you to have had more experience than any one of the Faculty now living not only in Cases of this inveterate nature but all others which Humane Bodies are lyable to. Be pleased therefore to know that this gentleman is of a pretty gross habit of Body but free as yet from any hydropical Symptoms, of a moist phlegmatick Constitution no way Subject hitherto to any other Inflammatory feavers but the Small pox which he hath given an Acel of in his Letter to Mr Gell the Bearer hereof: He is Scorbutick in the highest degree but whether it approaches towards the Lepra Græcorum must be determined by your riper Judgement as also whether some preparation from the Viper may not be of use to him together with due Evacuations and a long Continuance of proper Antiscorbutick Alteratives, & your wonted Candour and Humanity will give me leave to acquaint you that I have used the unguentum Citrium upon such Eruptions with good success in ordinary Constitutions but never without putting them under a Course of Physick for at least Six weeks together first. I heartly joyce that you Still, in Spight of Age honourably triumph at the head of the Profession: may you long continue so for the publiek good: and I desire you would recollect me to be Your old Sincere friend and most obliged humble Servt

New Castle in Emlyn  
Novr 13 1738

ALBAN THOMAS.

Sir Hans Sloane's directions for the treatment of this case, written in Latin in a crabbed hand and much contracted, are preserved with the letter. Dr. F. William Cock has been good enough to elucidate them for the benefit of our readers. The original runs as follows:

Veneseet. fol anthem. pulv. viper. bezoardici pts h. s. sine theriaca mane cum apozem: sudorifico. Elect. lenitiv. pro re nata merc. precipitat. et aq. muer. purge.

This, written out in extended form as a prescription, reads:

(Fiat) venesectio. (Recipe) anthemidis foliarum, pulveris viperæ bezoardici (pulveris) partes (æquales) horâ somni (sumendas) et cum apozemo sudorifico sine theriaca, mane. (Recipe) Electuarium lenitivum pro re nata. Purgé mercuriale precipitate et aqua minerali.

Rendered freely into English the prescription would read:

Bleed the patient. At bedtime let him have a powder made of equal parts of camomile leaves, powder of vipers, and bezoar stone. In the early morning let him have a sweating draught without landaunum. As a laxative, let him take the compound electuary of senna as required. To purge, give mercurial precipitate and mineral water.

Dr. Alban Thomas's letters are addressed: "To The Honble. Sir Hans Sloan Barrt. Presid<sup>t</sup> of the Royall Society &c. at his House in Great Russell Street Bloomsbury Square London." This address is curious, as Sir Hans lived on the south side of Bloomsbury, then known as Southampton Square, at the corner of the street of the same name, until in 1742 he retired to Chelsea.

The writer of these letters was a person of some note in his day, as we learn from a memoir written by Dr. Alban Evans and published in 1917 in the *Transactions* of the Historical Society of West Wales. Alban Thomas was an Oxford man, and, like many of his countrymen, of Jesus College. In 1708 he was librarian of the Ashmolean Museum, and in 1713 he was appointed assistant secretary and clerk to the Royal Society, of which at that time Sir Isaac Newton was president and Hans Sloane secretary. In 1718 he published a pamphlet entitled *A List of the Royal Society of London*, with the intention of popularizing the objects of the Society, and of making the scientific acquirements of the Fellows useful to the community. He does not seem to have taken his medical degree at Oxford, for in 1719 he received the diploma of M.D. from University and King's College, Aberdeen. In Meyrick's *History of Cardigan*, 1808, there is an account of the love affair which culminated in his first marriage. Like Viola in *Twelfth Night*, Thomas was employed by a friend to negotiate a marriage with a lady in London, who, like the Countess Olivia, intimated to the young physician that were he to woo her for himself he would not be unsuccessful. The rejected but chivalric friend insisted on the doctor's addressing the lady on his own account. He offered and was accepted, and the course of true love was only troubled by his supposed lack of gentility. This lack, his father, a grave divine and poet, quickly supplied by sending him his emblazoned genealogical tree, tracing his family in direct line to the Lords of Towyn. A happy married life followed, only too soon to end with the lady's death in childbirth.

Alban Thomas got into political trouble in 1723, when he was suspected of taking part in a Jacobite plot, and when the storm had passed over he retired to Wales, where he married a second time. He died in 1771. Of his library is extant a copy of the *Mikrokosmographia* of Helkiah Crooke, a tall folio dated 1615, but published in 1616, which he has annotated. This was a compilation, a "Description of the Body of Man," based upon the works of Bauhin and Laurentius, as Sir Norman Moore states in the *Dictionary of National Biography*, but ignoring, even in the second edition, the discoveries made by Harvey, although the latter's lectures on the circulation were delivered early in the year 1616. A finely bound copy is in the library of the Royal College of Physicians of London.

### MEMORIAL GATES FOR THE NEW BUILDING.

In the JOURNAL of January 10th an account was given of the progress made in completing and equipping the new headquarters of the British Medical Association in Bloomsbury, under the direction of the architect, Sir Edwin Lutyens, R.A. This included a brief note of the fact that ornamental wrought-iron railings and gates, to complete the main quadrangle and to serve as a memorial to members of the Association who lost their lives in the war, were being made by the Birmingham Guild, in consultation with the architect.

The work of fashioning the gates was begun in September last and is now almost completed; it is expected that they will be placed in position at the front of the courtyard in the course of the next few weeks. The design, for which Sir Edwin Lutyens is responsible, is generally based on the eighteenth century tradition of smith's craft in this country, with leaf-work and scrolls as the main feature. The decoration over the central gateway will

bear a bronze dedicatory tablet with the inscriptions "Memory and praise" and "Faithful hath been your warfare." The total width of the gates, with their screens, is 60 feet; the height, at the centre, is 24 feet. Arrangements for the official opening of the new house of the Association are proceeding, and it is expected that the opening ceremony, including the dedication of the memorial gates, will be in the early part of the week beginning July 13th.

The following note on the making of wrought-iron gates, by Mr. C. A. Llewelyn Roberts, managing director of the Birmingham Guild, Ltd., will no doubt be read with interest by many members of the Association.

#### *The Making of a Wrought-iron Gate.*

The traditional craft of wrought-iron work, practised in this country in the eighteenth century—largely influenced by Tijou's work, as seen, for instance, in the examples at Hampton Court—is now almost a lost craft. It naturally suffered from the change in style of architecture of later periods. During the Classic revival the craft still to some extent continued in the work of the Adam brothers, but it was gradually losing ground.

At the present day, therefore, in making a wrought-iron gate in this tradition a special effort has to be made to obtain the skilled craftsmanship which still does exist, and to direct its enthusiasm in the old methods. As far as these methods go, there is no great difficulty, because in the making, in the forging, and in the fitting of a gate the practice is the same as in the past; but, unfortunately, the artistic skill and the feeling given to the work of that period are not now so easy to obtain.

The actual gate starts with the design—of course, drawn to scale—and then full-size drawings are made of its form, in conjunction with the smith who is responsible for carrying out the work, so that the forms are such as may be really appropriate to the craft. On this matter the intimate technical knowledge of the smith is essential. These drawings being ready, the work can proceed. In the first instance, rolled iron bars of various sizes are obtained, and it may be mentioned in this respect that the rolled iron of the present day is largely inferior from the point of view of malleability and nature to similar material used in the past, which adds to the difficulty of the modern smith in getting the same results. The material being obtained, it is then, with regard to the plain bars of the gate, cut to the necessary lengths, and the upright members are fitted to the horizontal members by passing one bar right through a hole in another, or by being tenoned—that is, by forging the bar down to a peg at the bottom, fitting this into a hole in the other bar, and riveting over it; or, the bars may be "halved" together, a notch being cut out of each bar so that when together the bars are in the same plane; a rivet is then put through this joint. As regards this part of the work, representing the general framing of the gate, it is probably done better than it was in the past because more accurate mechanical appliances are available for the making of such joints.

When, however, it comes to the forging of the scrolls and leaves it is here that skilled craftsmanship must be united with artistic instinct to obtain results equal to those of the best masters of the past. The scrolls, of course, are forged and welded together—a process that any ordinary smith knowing his job can do. But the result depends upon the feeling of the smith for beautiful lines and forms, such as the good tapering of the work down from one end of the scroll to another, which gives character to the work and the form and outline of the scroll itself. There is no quick way about this: the success of such work depends entirely upon the knowledge and ability of the craftsman.

The leaves themselves are made out of thick rolled sheet-iron beaten up to the form required. It is often necessary to make the leaf red-hot during this process in order to obtain the relief required. When the leaf is made it is riveted through to the bar of the scroll work, and also welded to it, thus ensuring a perfectly strong fixing.

In the arrangements of the scrolls and leaves, although, of course, this depends primarily upon the design and the full size lay-out, nevertheless much is left to the smith doing the work. If he is unresponsive to the beauty of

what he is doing, even a slight disarrangement of the form may destroy the harmony of the result. But if, on the other hand, he appreciates the beauty of the arrangement of the forms and line, then he is more likely to enhance the success of the result.

The amount of labour in making up such a gate is far greater than one would imagine from the finished work, for there is not a part which has not received careful attention by the craftsman, the whole of it being done by hand throughout, except the purely mechanical fitting of straight bars.

## CONFERENCE OF MENTAL HOSPITAL AUTHORITIES.

(Continued from page 808.)

### PROVISION OF MENTAL HOSPITAL ACCOMMODATION.

THE second day's proceedings at the National Conference of Mental Hospital Authorities on April 22nd were devoted to the consideration of further mental hospital accommodation.

Sir FREDERICK WILLIS, Chairman of the Board of Control, who presided, said that the Board desired to direct the attention of local authorities and visiting committees to the serious need for the provision of additional mental hospital accommodation. At the beginning of 1924 there was vacant bed space in all county and borough mental hospitals for 4,754 patients; the average yearly net increase of patients for the four years 1920-23 was 3,565. The position as regards accommodation had somewhat improved by the beginning of this year. The net increase of patients during 1924 was only 1,508. But it was clear that the needs of the country as a whole rendered it essential that the provision of further accommodation in the near future should be considered. It might be practicable to make a fuller use of the provisions of Section 25 of the Lunacy Act, under which patients could be sent from mental hospitals to Poor Law institutions; of Section 26, which authorized contracts with boards of guardians for the reception of patients in those institutions; and of Sections 55 and 57, which allowed absence on trial and boarding out; and it was also suggested that more extended use might be made of the provisions of Section 79, under which suitable patients might be discharged to the care of relatives and friends. In some cases nurses might be lodged in hostels outside the institution, thereby liberating a certain amount of institutional accommodation. Some patients at present in asylums might properly be transferred to institutions for mental defectives. Notwithstanding every effort, however, it seemed necessary to face the question of providing new accommodation. In some instances it might be practicable to extend the accommodation in existing institutions by the provision of admission hospitals, the erection of separate villas, and such additions as might be determined by local requirements.

Dr. G. F. BARNHAM (Claybury) dealt with this last point. He supported the view that there should be admission hospitals, with villas for convalescents. A very large number of early cases required to be dealt with annually, far beyond the scope of the clinics. The large mental hospitals could afford greater scope for occupation treatment than any form of clinic could provide, and there was the highly important consideration that mental hospitals, deprived of a fully equipped admission unit capable of treating all varieties of mental disorder, must inevitably suffer in efficiency. Surely it would be possible to provide admission hospitals effectively dissociated from chronic insane patients and linked up with outside medical organization. To be effective the admission unit must be organized on the villa system, out of the sight and hearing of the main hospital, and must furnish means for the classification of cases, in addition to sex separation, together with sufficient provision of treatment rooms to meet the growing complexity of therapeutic measures. It was held in some quarters that hospitals of 2,000-beds were too large, but, on the other hand, the wealth of material, the facilities for research, and the education both of the medical and nursing staff increased with the size of the institution. He was of opinion that asylum authorities should not be afraid to enlarge their institutions, for additional accommodation could only add to the efficiency of the whole organization, besides being more economical.

A brisk discussion ensued, in which many chairmen of visiting committees and of asylum boards participated, and the possibilities of extended use of Poor Law accommodation, the sending out of cases on trial, boarding out, and discharge to relatives, the provision of admission hospitals, of nurses' homes, and general enlargement of the institution, were explored. Mr. C. L. FORESTIER-WALKER, M.P., suggested a series of regional conferences to discuss the problems and difficulties in the various areas, and it is probable that these will be arranged.

## PUBLIC HEALTH IN ITALY.

BY

PROFESSOR DR. ARTURO CASTIGLIONI,

MEMBER OF THE CHIEF COMMITTEE OF THE ITALIAN BOARD OF HEALTH;  
PROFESSOR IN THE UNIVERSITY OF PADOVA.

AFTER the war medical and university circles turned their attention to the study of the great problems of social hygiene and of preventive measures, strongly supported by the Government. Italian legislation has lately adopted many important hygienic measures, and both in Parliament and in medical associations hygienic questions are the order of the day. A most admirable institute was founded immediately after the war by Professor Ettore Levi, under the presidency of Luigi Luzzatti, the great statesman, repeatedly Minister of Finance and President of the Council of Ministers. This "Institute for Hygiene, Preventive Measures, and Social Assistance" collects all publications relating to the study of social hygiene, including propaganda work. Representatives of Ministries, large industries, chambers of commerce, banks, and of the working classes are collaborating in this work, which is outside politics, and operates from a social and economic point of view. The fight against infective and venereal diseases, and the welfare of infants, mothers, and of the working classes, are sustained by a most active propaganda through the means of books, lectures, courses of instruction, and schools—a propaganda which is conducted on parallel lines with those of other countries. The international relations of the institute secure the supply of much material for medical research, and doctors can study the statistics of all countries, the legislative measures applied by each, and their propaganda methods. For these reasons the Italian institute, which should be visited by foreign doctors coming to Rome, is just as important from a scientific as from a social point of view.

One of the problems which have most interested Italian scientists is the high mortality through tuberculosis during the great war and after. Immediately before the war—namely, during the period 1910-14—deaths through consumption were steadily decreasing, and had reached the minimum of 1,500 deaths per annum. In 1915 there was a sudden rise to 1,576, and during the three subsequent years the following figures were noted: 1,674, 1,749, and 2,090. The last figure is that of 1918, when there was a great epidemic of Spanish influenza in Italy. From that period onwards the figures gradually fell to a minimum of 1,423. It should be noted that during the first years of Italian statistics deaths through consumption stood at 2,128. All the above figures relate to one million inhabitants. Most important conclusions can be gathered from the above statistics, collected and published by Professor Niceforo of Naples University. First of all, they indicate that the war was indeed the cause of a sudden increase in tuberculosis, but that nevertheless the mortality curve did not reach the high point of 1887-89. It is interesting to observe a similar occurrence also in other important movements, not only relating to illnesses and to mortality, but also economic and social. Secondly, it must be noted that the decrease in deaths after the war brought down the curve of tuberculosis mortality to the pre-war point; this decrease, however, is not what it would have been had there been no war and had the same decreasing pace been kept up for tuberculosis.

*Preventive Medicine.*

In the Italian Congress of Social Eugenics, which took place in Milan a few months ago, several attending the Congress devoted deep study to the problem of precautions to be taken through legislation for the protection of future society from the perils of delinquency, drunkenness, and mental and nervous diseases generally, especially from the hereditary point of view. No practical result seems to have followed the adoption in some North American States of the "Act to prevent procreation," the object of which is to prevent criminals—and in some cases also idiots, mental defectives, and those afflicted with congenital insanity—from having children. The legislation for compulsory sterilization, proposed by the Laboratory of Experimental

Eugenics of Long Island, is still only a suggestion. Although at the Italian Congress it was recognized that the State has the duty of protecting, not only the individual, but also society and the race, the conclusion was nevertheless reached that it would be very difficult in practice to introduce similar measures in Italy. Efforts must therefore be made to prevent the reproduction of "undesirables" by instituting sanitary centres and matrimonial control. The first measure would serve the purpose of collecting all information relating to the various subjects, and of keeping an eye on their physical and mental development, from the strictly hygienic, the social, and the medical points of view. Matrimonial control should be established by requiring a medical certification of sound constitution and eugenic capacity before marriage. Professor Medea, who upheld these projects before the Congress, also pointed out how necessary it was to provide propaganda literature for the education of the people and for the development of an enlightened public opinion. In Milan, meanwhile, a psychiatric dispensary of the League of Mental Hygiene has been formed, not only for study and research, but also as a centre for active propaganda. Psychiatric social workers must attend to the unsound, and at the same time circulate useful knowledge.

In the fight against cancer and tuberculosis, especially as regards measures in early infancy, Italy has made a fine start this last year or so, and, thanks to Government support, new nursing homes, dispensaries, and open-air schools are constantly being opened. A great stimulus to the foundation of new institutions has been the King's suggestion that any act of homage Italians may like to render him on the twenty-fifth anniversary of his reign should take the form of public welfare work, preferably related to hygiene. Milan has set an example by founding an institute for cancer research. The Lord Mayor of Milan, Professor Mangiagalli, a senator of the kingdom and a famous clinician, has taken the initiative in this excellent work by collecting in a few weeks considerable sums of money, which will ensure the success of the enterprise. Many other towns have decided to found institutions for the fight against consumption, and throughout Italy there is a movement for organized activity which promises well, especially in the field of preventive measures. Italy, with her wonderful shores and the mild climate of her southern provinces, can construct a really practical programme in this sphere of work, especially in connexion with the welfare of infants. All the associations engaged in this fight against consumption will meet in a congress to be held at Naples from May 25th to 28th. This congress, keenly awaited in medical circles, will discuss such particularly important questions as treatment in mountain nursing homes, on the sea coast, and in nursing homes on plains. The problem of preventive vaccination will also be fully discussed.

An exhibition will take place at the same time, at which the leading nursing homes and health institutions will be represented, and where apparatus and preparations for the cure and diagnosis of consumption, and literature on antituberculosis associations and legislation, will be on view. Naples is a peculiarly suitable place for this congress, since it was the first city in the world where the Government—at the instigation of the famous doctor Domenico Cottugno—issued an order in 1782 that doctors should notify all cases of consumption, and founded a special hospital for consumptive persons.

During the recent discussions in the Italian Parliament on the budget for the interior, doctors repeatedly urged the Government to take greater interest in hygienic problems. The Hon. Professor Messedaglia recommended the adoption of stronger measures for the definite conquest of malaria, and, supported by medical deputies, a bill was advanced limiting the number of establishments for the sale and consumption of alcoholic drinks to one establishment per 1,000 inhabitants, instead of one per 50, as fixed by law in 1913. At the same time the sale of wine, beer, and other alcoholic drinks is to be forbidden after 11 p.m. and before 10 a.m. The Italian Association for Hygiene, presided over by Professor Achille Sclavo, rector of Siena University, has performed splendid work in the fight against alcoholism;

it has also asked that special homes for inebriates should be opened, and that the Government should consider the possibility of modifying the article in the Penal Code which enacts that drunkenness lessens the crime instead of increasing it. The general decrease in cases of drunkenness which has been observed in Italy after the war, decrease being also noticeable in the consumption of alcoholic drinks, is due to a great extent to the Government's restrictive measures, and it can therefore be expected that the propaganda of hygienic institutions, especially in schools, will result in a gradual but marked decrease in delinquency.

#### New Universities.

Two new universities were opened in Italy this year, regardless of the opinions of most learned men, who think that the existing universities are already excessive in number. However, the Government has introduced English methods into its new university law by declaring that new universities may only be opened, and minor universities be maintained, if the borough or province is willing to bear the bulk of the expenses relating thereto, assisted by a small Government contribution. Milan has quickly collected funds and opened a first-class institute, specially designed for medical studies. The clinics, already in existence as schools for graduation (noteworthy amongst them the clinic founded and run by Professor Devoto, a leader of the Italian medical faculty), have all passed under the control of the new university, which has also opened a number of new institutes, appointing some of the best known Italian scientists to run them. In view of the progressive development of the city of Milan, the centre of Northern Italy's industries and commerce, and thanks to the energy with which Senator Mangiagalli, who is also the rector of the university, has undertaken his task, it can confidently be asserted that the University of Milan will soon hold a leading place in Italian scientific circles. Another university with a medical faculty has been opened in Bari (South Italy), which hitherto only had the University of Naples. The Bari University also has some fine medical institutions; its rector is Professor Pende, whose name is well known for his studies in endocrinology and pathology.

## Scotland.

#### THE EFFECTS OF HOUSING ON EPIDEMICS.

At a meeting of the Public Health Subcommittee of Edinburgh Town Council on April 21st, Dr. William Robertson, M.O.H., submitted a report on the effect of housing on the spread of infectious disease. Since the long and serious epidemic of measles and whooping-cough began, 3,315 cases of the former and 1,764 cases of the latter had been notified, 548 cases of measles and 259 cases of whooping-cough had been treated in hospital, and the number of visits paid by nurses was 2,996. Much difficulty had often been experienced in caring for children in houses that were on the border-line of being overcrowded. Subletting was a regrettable feature of the housing shortage, and instances had been met in which two families were attempting to live in two- and three-roomed houses. Under such conditions, when measles or whooping-cough broke out the spread of infection became unavoidable, and the proper nursing of infected children in such circumstances was almost impossible. The congestion caused by the tenement system, where too many families lived in too close contact with one another, and where the children were compelled to rub shoulders in the long passages and lobbies of three- and four-storied buildings, was another great factor in infection. Experience had shown that large numbers of the cases occurred in houses entered by common stairs.

#### PURE MILK COMPETITION.

On the suggestion of the Board of Agriculture for Scotland, a competition was recently organized by the Public Health Committee of Edinburgh Town Council for dairymen within the city boundaries. Councillor Harvey, Convener of the Public Health Committee, who presided at the prize distribution on April 16th, said that the success attained had

fully justified the enterprise; the competition had shown that any dairy byre in the city might produce milk of Grade A standard. Investigations made by the veterinary department of the city some time before the competition had shown that 37 per cent. of the retail milk sellers in the city were selling milk which conformed to the Grade A standard, which was essentially clean milk, with a very low general bacterial content, and practically no coliform organisms. The earlier regulations had been principally directed towards the cow and the cowshed, but under the new regulations more attention was paid directly to the milk, and its source of supply was considered immaterial so long as the product itself was satisfactory. The Public Health Committee was satisfied that the supply of milk from within the city boundaries would be more easily and efficiently supervised than a supply from outside. Under existing legislation the powers of local authorities to give practical assistance to the milk industry were limited, but local co-operation and harmonious co-ordination between the authority and the trade was possible. Sir Robert Greig, Chairman of the Board of Agriculture for Scotland, congratulated the Public Health Committee and the competitors upon the fact that the competition was the first of its kind in this country. Few countries produced a better or larger supply of clean milk than the United States of America and Canada, and yet in those countries milk was often produced in buildings which our local authorities in this country would not allow for that purpose. There was an almost unlimited field for the production and consumption of milk, but consumers had not yet been educated up to the fact that milk was one of the cheapest and most valuable of foods. In America people consumed about three times as much milk a head as we did. In Chicago cars might be seen going around with bottles of milk which workmen bought in the street and drank, but they had a long way to go in Scotland before they would find the average workman stopping to drink a bottle of milk. Medals and certificates of merit were then presented to the dairy workers.

#### CHANGES IN FOOD SUPPLIES.

At a meeting of the Council of the Scottish Federation of Grocers' and Provision Merchants' Associations, held in Edinburgh on April 15th, it was intimated that a letter had been received from the Scottish Board of Agriculture referring to the declining consumption of oatmeal in Scotland, and asking six questions. The Federation replied that the decline in the consumption of oatmeal which had become apparent before the war was to be attributed to a change in the national diet; practically every household had ham and eggs or fish for breakfast, and the average housewife would not cook two courses, so that porridge was left out. The decline in consumption was over 50 per cent., judging by the sales of oatmeal twenty-five years ago. The consumption of flaked oats and similar preparations was increasing and might in part account for the smaller use of oatmeal, although people as a rule preferred home oatmeal to foreign oatmeal. The Federation thought that enterprise in advertising and educating the public would soon stimulate the demand. The Federation had sent a deputation to the Board of Health to represent that serious disturbance would be occasioned if the use of preservatives in foods was entirely prohibited, as proposed in the draft regulations recently issued. The deputation had suggested also that labels on articles containing permitted preservatives, upon which was stated the amount of preservative present, would serve no useful purpose, but would alarm consumers; it would be sufficient if the label stated that the article "contained preservatives conforming with the Board of Health regulations." The opinion was advanced that cold storage could never take the place of preservative because facilities throughout the country were quite inadequate.

#### CARE OF THE BLIND.

At a social meeting of the directors in the industrial section of the Royal Blind Asylum and School, Edinburgh, Mr. Ewan F. McPherson, Chairman of the Scottish Board of Health, said that any help given to remove the handicap from which the blind suffered was, until lately, voluntary. Edinburgh had given a lead to the country in this respect

for the asylum had now been established for 132 years and at the present time 350 blind persons were being helped. By the Act of 1920 the duty of doing something to promote the welfare of the blind was placed upon town councils and county councils. It had taken some time to get the Act into operation, but the town and county councils, education authorities, and voluntary institutions were co-operating, and before very long every blind person who was suited in any way for any occupation would get such training as would fit him or her for that occupation.

#### DUNDEE MENTAL HOSPITAL.

At the quarterly meeting of the directors of the Dundee Royal Mental Private Hospital, Dr. A. B. Dalgetty, medical superintendent, reported that during the quarter 75 persons had been treated, of whom 5 had been voluntary patients. Voluntary patients recovered as a rule more quickly than the others. Some voluntary patients had remained in the hospital for six months, twelve months, and more.

#### CARE OF THE CHILD IN SCOTLAND.

The annual general meeting of the Royal Scottish Society for Prevention of Cruelty to Children was held in Glasgow on April 22nd. Lord Provost Montgomery, who presided, in moving the adoption of the report, said that last year the society had dealt with 7,583 cases, representing 22,156 children, who were visited throughout Scotland. Sir John M. Macleod, Bt., in seconding the report, said that one of the striking features of the changes in progress to-day was the desire on the part of one section of the community that all activities should be centralized, including the activities of benevolent and charitable institutions.

#### Ireland.

##### THE LATE PROFESSOR A. C. O'SULLIVAN.

SHORTLY after the death, last year, of A. C. O'Sullivan, M.D., S.F., professor of pathology in the University of Dublin, a committee was formed to collect funds in order to perpetuate the memory of his connexion with Trinity College, and especially with the School of Pathology, of which he was for nearly thirty years the head. Over £1,000 has been collected, and with this sum a scholarship has been founded in the School of Physic. The O'Sullivan Scholarship, valued at about £48 a year, is to be awarded, on the nomination of the School of Physic Committee, without examination, to the most deserving candidate, consideration being given to his record in the medical school, in the University generally, and also to his financial circumstances. Besides the foundation of the scholarship a bronze tablet has been erected in the School of Pathology, which bears the following inscription:

ALEXANDRO CAROLO O'SULLIVAN  
HUIUS COLLEGI SOCIO  
PRIMUM OBSTITUIT  
LUGENS UNIVERSITAS  
HOE MONUMENTUM POSUIT  
MEMXXIV

The tablet was unveiled by the Provost of Trinity on April 21st. After a statement by the honorary secretary, Mr. E. J. Gwynn, relative to the collection of the fund and its application, Dr. W. G. Smith, on behalf of the subscribers, presented the scholarship and tablet to the school. In the course of his speech, he said that they were assembled to pay the last possible mark of respect to the memory of a man of "infinite variety" and one endowed with remarkable intellectual gifts, who had been prematurely taken away. His versatile and nimble brain was equally at home in the favourite subject of mathematics, or in languages, or in the practical work of the laboratory, or in the deft use of his hands as an expert craftsman. He had cultivated with such success his special subject of pathology that he was acknowledged as an authority. The Provost, accepting on behalf of the college the scholarship and memorial, thanked Dr. Smith, the senior Fellow of the

Royal College of Physicians, for what he had said. No one in recent years had so well carried on the old Trinity College tradition of general culture as distinct from merely professional knowledge as Dr. O'Sullivan. He had an austere sense of the meaning of exact knowledge, and very patient of anything like humbug or pretence, and very scornful of half-knowledge. The only other adjective used of him in the felicitously worded inscription was "magnanimus"—great-hearted, great-souled—and that explained why he had so many friends. The Provost spoke feelingly of his long friendship with Dr. O'Sullivan, extending from the days when they were undergraduates together. He was glad that a permanent memorial to Professor O'Sullivan would rest in the School of Pathology, to which he devoted himself more and more as the years passed by, and that so his name would be kept before the generations to come. The Provost then unveiled the memorial, to which many friends and former pupils of Professor O'Sullivan, scattered over the world, will be glad to know that now a permanent memorial has been erected in Trinity College, which he served so faithfully all through life and which he loved so well.

#### England and Wales.

##### HEALTH PROPAGANDA.

THE Minister of Health, the Rt. Hon. Neville Chamberlain, M.P., received on April 23rd a deputation from the Society of Medical Officers of Health, introduced by Dr. J. Wheatley. The deputation represented that they, in their capacity of men of scientific training in constant touch with the general public, had found that there was an urgent need for further propaganda directed to the general improvement of health rather than to the combating of special diseases. They thought that statutory provision should be made for local authorities to carry on health propaganda. As a next stage a central body should be set up to advise local authorities, who sought their help on the way in which propaganda should be carried out locally, and to assist them by the provision of lecturers, literature, and other means of propaganda which could best be organized by some special central authority. The society thought that in its position it would be able to give valuable help to such a central body, and that medical officers of health should themselves be included in its membership. The Minister, in reply, said that he fully agreed with the deputation as to the necessity for propaganda on health questions, and he gave his assurance that he proposed to take steps to have the necessary powers conferred on local authorities forthwith. He hoped it might be possible to do so this year, or, at any rate, next year. He also agreed that some sort of central body could give valuable assistance; and when the necessary legislation had been passed he would give careful consideration to the question of the proper constitution of such a body and the functions which should be assigned to it.

##### CARE OF MENTAL DEFECTIVES.

DURING the last ten years the Leeds Voluntary Committee for the Care of the Mentally Defective has undertaken the supervision of those mental defectives who are not resident in institutions; altogether 738 have been dealt with, and at present 436 are under supervision. The home conditions in the case of 135 of these defectives were considered unsatisfactory, and the annual report of the committee draws attention to the evils arising from intensive overcrowding of these defectives. Systematic visiting of the homes has produced good results, but as there is no statutory obligation on the parent or guardian to co-operate with the local authority in promoting the safety and well-being of the defective, a certain number of the mentally deficient become a menace to the community. It is suggested in the report that since such supervision is an established method of dealing with the mentally defective classes the obligations and responsibility of parents and guardians ought to be specifically defined. The Leeds committee was the first in the country to provide an employment centre for feeble-minded youths and men, the industries being boot-making

and repairing, rug and mat making, and wood chopping and bundling; fifty-one persons were employed at the centre during the year. The average sales amounted to £12 a week, as compared with £10 in the previous year. Small allowances were made to those under training, and, in addition, many had their boots repaired and their clothing supplied without cost. The centre has already resulted in a financial saving to the local authority, since but for its existence at least ten of the defectives now accommodated there would have had to be maintained in certified institutions, where each would have cost not less than £60 a year.

#### KING EDWARD VII SANATORIUM, MIDHURST.

The eighteenth annual report of the King Edward VII Sanatorium, Midhurst, shows that 294 patients were admitted to the sanatorium during the twelve months ending June 30th, 1924. They included 20 readmissions and 19 who remained in residence too short a time to be considered in the record; during the same period 234 patients were discharged. The demand for beds has remained steady, the average number of applicants on the weekly waiting lists being: for men 6.3, for women 6.7. Treatment by graduated rest and exercise remains an important part of the sanatorium routine. Results are given of the treatment of eight patients by the induction of artificial pneumothorax. The report also includes an account of the work of the statistical department, relating to approximately 4,000 cases discharged from the sanatorium.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### The Budget.

THE Chancellor of the Exchequer introduced the Budget on Tuesday last. The reductions in income tax and supertax are of particular interest to many individuals, but the most important part of the financial scheme Mr. Churchill unfolded is the extension of State insurance. It includes pensions for widows and orphans, beginning next January, and a reduction of the qualifying age for old age pensions from 70 to 65, to begin in January, 1928.

Mr. Churchill said that the consuming power of the people was maintained, and thrift continued, despite unemployment and trade depression. Floating debt had been reduced during the past year by £32,500,000 and external debt by £4,000,000. Larger funding operations would be undertaken in the lifetime of the present Parliament. This year £50,000,000 would be devoted to the Sinking Fund. The country had been paying off war pensions on a considerable scale. In 1919 the total capital liability for pensions had been £1,000,000,000, and the yearly expenditure £100,000,000. That capital liability was now reduced to £760,000,000, and the annual charge £67,000,000. A strict perseverance in paying off pensions would relieve the taxpayer by a further £2,000,000 or £3,000,000 each year. The Government had decided to allow the restrictive legislation against the export of gold to lapse on December 31st and to issue, till then a general licence for the export of gold and bullion. To reintroduce gold coinage at present would be an unwarrantable use of notes must be paid for. The public interest had been made for the year, and further credits were available in America. The estimated expenditure of 1925-26 was £799,436,000; this was disappointing. He trusted that a period of settled government would permit the overhauling and reduction of expenditure. After this year reduction of taxation could only be achieved by reduction of expenditure. Improvement in trade would only be gradual, but he was not providing for any war abroad or for industrial convulsions at home. He was not budgeting for any repayments from European Allies, but they should not relax their efforts to obtain such repayments. He estimated that in 1925-26 the total receipts from taxes would be £711,000,000, against £689,702,000 last year. The income tax was estimated to yield £289,000,000. Customs and Excise £235,000,000, and motor vehicle duty £17,500,000. Receipts from non-tax revenue he estimated at £114,500,000, making the total estimated revenue for 1925-26 £826,000,000.

### Death Duties.

The Budget surplus was £26,500,000, a sum satisfactory in itself, but not adequate to achieve the two great purposes of public policy—security for the home of the wage-earner and relief for the hard-pressed on industry. It was imperative that he should fortify the revenue, and his scheme for doing so must be judged as a whole. Death duties on estates over £12,500, but not on the greatest estates, would be increased to yield £1,500,000 this year

and £10,000,000 in a full year. Between £12,500 and £18,000 the death duty would be increased by 1 per cent; on £40,000 by 3 per cent., on £175,000 by 6 per cent. Thereafter the percentage increase would diminish, and an estate of £1,000,000 would be taxed as now.

### Luxury Taxes.

He proposed that the House should impose luxury taxes which no one would need to pay. One of these would be a new revenue duty, calculated by weight, on silk, natural or artificial, raw or semi-manufactured. A certain advantage would be given to the home producer. The revenue would be £4,000,000 this year, and £7,000,000 in a full year. In place of the hop control which was about to lapse, a duty on imported hops was to be levied, for four years, to produce £250,000 in a full year. The "McKenzie duties" on motor cars and other goods would be reimposed, with the silk duties, from July 1st. The total yield of all these "luxury taxes" would be £5,300,000 in the first year and £10,000,000 in a full year.

### State Insurance and Old Age Pensions.

Mr. Churchill announced that legislation would be proposed improving the income tax machinery and amending the success duty law. He then turned to his proposals for improving State insurance, which, he said, though imperfect, was pre-eminent among the insurance systems of the world. The first object was to provide old age pensions before 70. The scheme, to be of use, must be contributory and compulsory, and must cover the whole wage-earning population of 15,000,000 who now came under the National Health Insurance Acts. It had been decided that in addition to the insurance payments now made 4d. could be paid by every man and 2d. by every woman in employment, and that the employers could also pay an additional 4d. per man and 2d. per woman. If all workers contributed from the age of 16, 10s. a week could be paid to widows and 10s. to the old worker at 65. A sum of 1d. for each insured person would be transferred from health insurance and unemployment insurance to the new scheme, which by the aid of a State contribution could be brought into operation by stages from January 4th, 1926. The present capital value of the additional liability to the State was computed at £750,000,000.

Mr. Churchill warned the House that, apart from the new pensions scheme, the Government's actuaries predicted a great growth in old age pensioners under the existing scheme because the span of human life was being prolonged and the survivors of the large increments to population in Victorian times were reaching pensionable age. The census of 1891 showed 5,200,000 persons between 40 and 50; that of 1921 showed 9,700,000 between those ages. The present annual cost of the existing old age pensions was £27,000,000. In ten years it would be £36,000,000; in twenty, £40,000,000; and in fifty, £60,000,000. This island in thirty years would have more than double its present old and feeble people and would have to support them with little more than its existing active population. To meet this, the contributions of employers and employed to the new pensions scheme were to be raised by 1d. per man and 4d. per woman each decade. By the tenth year the annual cost of the new scheme to the State would be £15,000,000, and by the twentieth £24,000,000. Thereafter it would decline. After 1926 the contributions to the new scheme would cover the existing old age pensions as well. The new scheme would cost nothing in the first year to the State. It was only from the third full year that the charge began to operate. The charges would be averaged over ten annual instalments approximating to £5,750,000 each year from 1926. A bill dealing with the scheme would shortly be introduced by the Minister of Health.

Widows of all men insured in the national health insurance scheme who became insured in the new scheme would get 10s. a week from January 4th next, with 5s. for the first child and 4s. for other children. All existing widows of men who were insured, if those widows were now mothers, would receive the same benefit as a gift till six months after the youngest child reached 14. The scheme affected 230,000 widows, and its capital value to each was £600. There would also be grants for motherless orphans. The progressive fall in war pensions would more than offset the cost of the new scheme.

Mr. Churchill further announced that from January 6th, 1928, all workers who had contributed for five years to national health insurance and for two years to the new scheme would receive 10s. a week at 65 without any means test. The same benefit would be paid to their wives at 65. All restrictions and means tests on old age pensions after 70 were to be swept away from July 1st, 1926, and about 100,000 would benefit.

### Income Tax and Supertax.

Turnip to remission of taxation, Mr. Churchill announced preferential remission of duty on Empire dried fruits, tobacco, wines, and sugar. The supertax was to be reduced to correspond with the increase in the death duties, thus encouraging the creation of new wealth. The rates of supertax would be halved up to £3,000, with lesser remissions thereafter. In income tax further advantage would be given to earned income. At present the allowance for earned income was one-tenth up to a maximum of £250. That would be increased to one-sixth, up to a maximum of £250. This deduction could be made in full on incomes up to £1,500. Persons over 65 with incomes of less than £500 would be granted this earned income relief, which would cost £3,000,000 this year and £7,500,000 in a full year.

Mr. Churchill concluded by announcing that in addition 6d. was to be taken off the standard rate of income tax, making it 4s. in the £. This would cost £24,000,000 in the first year and £32,000,000 in a full year.

The criticism of the Budget which was offered by Mr. Snowden and Mr. Lloyd George was very cautious and not hostile.

## Correspondence.

### THE MORTALITY OF APPENDICITIS.

SIR,—The excellent and thoughtful papers of Mr. Joseph E. Adams and of Mr. James Sherren (*JOURNAL*, April 18th, pp. 723 and 727) once more direct attention to this subject. Their information is so complete and their arguments so moderately stated that I should hesitate to intervene were it not to join in the note of warning which you so promptly, and I think wisely, sound in your leader in the same issue.

All surgeons must know that many cases of appendicitis spontaneously recover, even when complicated by peritonitis or abscess, but that many only do so after running the gauntlet of a long and dangerous illness. Even when under observation and control in hospitals disappointments occur, and they frequently happen when attempts are made to treat patients on conservative lines in their own homes.

I have watched the progress of the surgery of appendicitis in this district for over a quarter of a century, and during this time I have experienced the results of the recurring advocacy of the delayed operation. Every time this plan has been written about in the medical press and generally discussed, it has almost at once been followed by an increased mortality. The conduct of the case on conservative lines is not reserved for the operating surgeon who ought to be responsible, but is undertaken by another section of the profession, and in the hope of avoiding operation is eagerly accepted by a not inconsiderable section of the public. This delay is lightly countenanced; some cases are allowed to develop general peritonitis; many abscesses occur, many fortunately localize or remain so, but too frequently complications and a lengthier stay in hospital follow, and in the long run the mortality always rises.

The following is a record of my personal operations up to the end of 1924.

#### Mortality of Appendicitis: Personal Experience.

	Cases.	Deaths.	Percentage.
Group 1.—Acute appendicitis without peritonitis	102	0	—
Group 2.—Acute appendicitis with localized peritonitis	366	4	1.09
Group 3.—Acute appendicitis with flank or pelvic peritonitis or both	187	15	8.02
Group 4.—Acute appendicitis with diffuse peritonitis	89	26	29.21
Group 5.—Appendicitis with residual abscess	62	5	8.06
Group 6.—Appendicitis with primary localized abscess	373	10	2.64
Group 7.—Appendicitis—interval removals	725	3	0.4
Group 8.—Appendicitis with primary complications	19	8	42.1
	1,938	71	3.65

All the cases for which I have been responsible are included. Group 8 comprises complications like intestinal obstruction associated with acute appendicitis, pyelophlebitis, and so forth, so that the percentage mortality must needs be high, but these cases are included for the sake of completeness.

I believe that, however the figures are used, they show that the mortality rises with the march of pathological processes. The latter do not attend on the clock, and a recognition of this fact long ago made me give up a classification of cases based merely on lapse of time. One patient may show an unlimited and severe peritonitis in less than twenty-four hours, whereas in another the inflammation may always remain localized.

Recognizing my responsibility as a teacher, I would strongly urge that every case of appendicitis should be operated upon while the disease is active. Only in a few fulminating cases the surgeon must know "no night, no day," but there should be no undue delay, though the surgeon of experience may recognize that the case may safely await his convenience from, say, late at night to the next morning, or from one day to another, and so forth. There are also cases in which some delay may be an

advantage—to combat toxæmia, to allow the effect of drugs to pass off, to move the patient to better surroundings, etc.; but these considerations do not affect the general rule that an attack of appendicitis should be cut short by operation. The scope of the operation is a very different matter, and that must vary with the pathological conditions present and with the experience of the surgeon. A timely incision under a local anaesthetic, or the puncture of a pelvic abscess, may each save the life of a patient, so that the appendix may be removed later to prevent so serious a risk recurring. As a matter of fact, in over 95 per cent. of my own cases the appendix has been removed at the one and only operation.

But appendicitis must surely always have a mortality—and mainly the mortality of the occasional difficulty in diagnosis. Last year I had 85 cases without a death. So far this year there have been two deaths—one because some bronchial trouble associated with one of the exanthemata in a child led us to adopt the policy of the delayed operation; and one because the patient himself delayed too long before seeking the advice of his doctor. And even interval operations have some mortality.—I am, etc.,

Newcastle-upon-Tyne, April 23rd.

G. GREY TURNER.

### RECENT ADVANCES IN THE STUDY OF CARDIO VASCULAR DISEASE.

SIR,—Dr. Harrington Sainsbury, in his letter (*BRITISH MEDICAL JOURNAL*, March 28th, p. 633), questions whether the modern instrumental methods have led to a real advance in the study of cardio-vascular disease or if they have merely led to changes in our points of view. I am afraid this must remain a matter of opinion.

In his comments upon my reference to the effect of Sir James Mackenzie's work upon clinical cardiology, Dr. Sainsbury discusses some defects of the polygraph and restates his views regarding the uncertainty of the physiological interpretation of the venous pulse tracing as recorded by this instrument. That physiologists do not consider the present interpretation of the various waves upon a phlebogram as settled is evidenced by Professor Barry's recent work, in which he records this pulsation by an optical method.

In consideration of the significance of venous pulse records due attention must be given to the experimental evidence brought forward by those who are engaged in the investigation, by modern methods, of the true time relationship of the various events in these records. Dr. Sainsbury appeals to those teaching to look into this matter with an open mind, and I feel certain his views will receive full consideration.—I am, etc.,

Belfast, April 20th.

J. E. MACILWAINE.

### TREATMENT OF DIABETES BY RAW FRESH GLAND (PANCREAS).

SIR,—In a recent communication to the *BRITISH MEDICAL JOURNAL* (March 14th, p. 503) Dr. T. J. Hollins stated that when a patient with diabetes mellitus was given raw pancreas by mouth the sugar disappeared from the urine, and, further, that this line of treatment did not cause any symptoms of overdosage. Dr. W. Dunn (April 4th, p. 680) stated that he had had good results on one patient, but Dr. G. A. Harrison (April 18th, p. 760) failed to confirm these observations on two patients, who had been under treatment for some time. This subject is of importance, since a patient would much rather take a medicine by mouth than have it injected every day. An attempt was therefore made to confirm Dr. Hollins's work.

The patient, a girl aged 14, had been under treatment for the past two years, but her sugar tolerance had decreased, chiefly owing to the unsatisfactory conditions in the home. The dose of insulin was increased rapidly from 5 units to 12 units in the morning and another 8 units at night. After three weeks the blood sugar at 10 a.m., before the insulin injection, was normal, and the dose of insulin was reduced to 8 units in the morning and 6 units at night, owing to some slight symptoms of hypoglycaemia. The blood sugar for three days before the experiment varied from 0.12 to 0.14 per cent. The diet was kept constant at sugar

16 grams, protein 82 grams, fat 134 grams, caloric value 1,600. Weight of patient, 68 lb. The pancreas was supplied by the British Drug Houses, Ltd., and I wish to thank them for their courtesy in sending it. It was kept in an ice-chest, since insulin is not destroyed under these conditions. One ounce was eaten at 10 a.m. each day with salad, and the girl did not object to it.

		Blood Sugar.	
		10 a.m.	4 p.m.
April 2nd	...	0.125 per cent.	0.14 per cent.
" 3rd	...	0.15 "	0.21 "
" 4th	...	0.215 "	0.225 "

Sugar appeared in the urine on the afternoon of the second day and was present in every specimen passed on the third day. The experiment was then stopped and insulin given for the next two days. Since the frozen raw pancreas had failed to maintain the blood sugar within normal limits, it was conceivable that some change had taken place as the result of the freezing. The pancreas was therefore sent direct from the slaughterhouse (packed in a little ice) and was given to the patient as soon as it arrived. This was a little inconvenient as the time of arrival varied from 1 p.m. to 4 p.m.

On the first two days 2 oz. were given and 4 oz. on the third day.

		Blood Sugar.	
		10 a.m.	4 p.m.
April 6th	...	0.14 per cent.	0.13 per cent.
" 7th	...	0.175 "	0.19 "
" 8th	...	0.18 "	0.215 "

Sugar appeared in the urine on the afternoon of April 7th, but was absent on the morning of the third day, although in the whole twenty-four hours 12 grams of sugar were excreted. In order to complete the experiment insulin was given for the next few days, and in the following three days neither insulin nor raw pancreas was given, so as to demonstrate the effect of the pancreas.

		Blood Sugar.	
		10 a.m.	4 p.m.
April 14th	...	0.115 per cent.	0.12 per cent.
" 15th	...	0.145 "	0.145 "
" 16th	...	0.14 "	0.15 "
" 17th	...	0.16 "	0.15 "

Insulin started.

April 18th ... 0.115 per cent.

The experiments on this patient, together with those reported by Dr. Harrison, seem to show quite clearly that raw pancreas, when eaten, does not have any effect in lowering the blood sugar of the patient who requires insulin to maintain it at the normal level. In this case, the amount of insulin required was only 14 units, but in both experiments the blood sugar began to rise about twenty-four hours after the insulin had been stopped. When neither pancreas nor insulin was given, the blood sugar did not rise as high as when the pancreas was given, but this may be due to the extra food, which was eaten in the form of pancreas, since no reduction was made in the other constituents of the diet.

These experiments do not hold out any hope that raw pancreas can be of any assistance to the patient with true diabetes mellitus who needs insulin.—I am, etc.,

London, W.1, April 25th.

GEORGE GRAHAM.

Sir,—Dr. G. A. Harrison in his letter (April 18th, p. 760) twice mentions that "the dose of insulin remained constant." Dr. Hollins (March 14th, p. 503), Dr. Young (March 28th, p. 632), and also Dr. Dunn (April 4th, p. 680), all three explicitly state that no insulin was being used. What becomes of Dr. Harrison's argument?—I am, etc.,

EDWARD B. FENNELL, M.D.

Hayle, Cornwall, April 24th.

#### INFLUENZAL MYOCARDITIS.

Sir,—During the recent influenzal outbreak I was struck by the fact that in almost every case, although the attack itself was often very mild, the convalescence was prolonged, and characterized by symptoms and signs which pointed to invasion of the myocardium by the toxin and the production of incapacity for work for an average period of four to six weeks in many cases.

The typical history given by patients was that the attack was so slight that they did not think it necessary to consult a doctor, but, following the attack, they were seized with

giddiness, faintness, breathlessness, and exhaustion. An examination of the heart revealed a somewhat rapid pulse, 80 to 90, of low tension, and irregular, and in the majority of cases there was a definite displacement of the apex beat 1/2 in. to 1 in. outwards, showing slight dilatation. Auscultation generally revealed a tic-tac rhythm, and occasionally a systolic murmur developed at the apex, but disappeared when the apex travelled in again, and the symptoms of cardiac insufficiency disappeared. Some cases were characterized by bouts of simple tachycardia and trembling of the limbs, the patient comparing his sensations to the staggering gait of a drunken person. The complexion in the majority of cases was sallow and the eyes sunken, and the cardiac symptoms were accompanied by a loss of flesh and anorexia. The symptoms generally took two months to disappear completely, and in cases of pre-existing heart trouble a longer period was required.

I find that the administration of salicin in 20-grain doses every two hours for the first twelve hours and then every three hours for the next twelve hours, as advised by E. B. Turner, has a valuable effect in protecting the heart, and should be given with the regularity of salicylates in acute rheumatism.—I am, etc.,

Stafford, April 25th.

C. JOYNER, M.A., M.B., Ch.B.

#### SLOW HEART.

Sir,—The Observer for April 26th, in a long article by a special correspondent on Nurmi, "the world's greatest athlete," mentions that "Nurmi's heart, even under stress, beats only 44 to 49 times to the minute." The article also recalls that at Stockholm, on August 23rd, 1923, Nurmi set up a new world's record for the mile of 4 min. 10½ sec., and that at the Paris Olympiad, last year, he won the 1,500 metres, 5,000 metres, 3,000 metres team race, and the 10,000 metres cross-country race. As many of your readers will know, Nurmi is still astonishing the athletic world. But it is the mention of his heart rate (44 to 49) which prompts this letter, particularly as a week ago I saw a lady, aged 30 years, whose pulse was 27 and next day 28 to the minute. She was not complaining of her health, and I had only felt her pulse because, when I said the pulse of her son, whom I was attending, was slow (50) she said it might be a family complaint.

In a long experience I can remember only one case of such very slow pulse unassociated with complaint of ill health, and that was one of a gentleman who died in his 80th year. His pulse, when he considered himself feeling well, used to be 28 a minute. He had the slow pulse during the last fourteen years of his life—I did not know him before—although during the greater part of that time he was active and took considerable walking exercise. Six months before he died he developed marked Cheyne-Stokes respiration, which he had for a week or more, but recovered, and was up again for several months.

I think that some of your readers may be interested in these details. I should be glad to hear the opinions of others on this subject, as I regret I am unable fully to explain the condition myself.—I am, etc.,

London, W.14, April 26th.

RICKARD W. LLOYD.

#### THE TREATMENT OF INFANTILE PARALYSIS.

Sir,—I have read with much interest the various letters that have recently appeared in the JOURNAL on re-education treatment for infantile paralysis. I must, however, point out that Mr. P. B. Roth is not quite right in his letter (April 4th, p. 681) when he states that priority of the methods is to be given to his grandfather, Dr. M. Roth, who published a book on the treatment of paralysis in infancy during 1869. While in no way wishing to detract from the good work done by Dr. M. Roth, in justice it must be stated that his methods were essentially those of the Ling school, who had been treating various forms of paralysis, including infantile paralysis, for many years previously. A case of the disease in question treated by re-education can be found described in the *Archiv für pathologische Anatomie*, 1859, xvi, pp. 177-191, by Dr. M. Eulenburg.—I am, etc.,

London, W.1, April 26th.

EDGAR F. CHALK.

## INDIVIDUAL MEDICAL DEFENCE.

SIR.—In your issue of April 25th (p. 806) Dr. Henry Robinson writes at some length criticizing the suggestions for individual medical defence made by the Council of the Association in its Annual Report (paras. 50-58) and summarized in its recommendation to the Representative Body.

Those who are in doubt as to whether the Association should undertake this work should study Dr. Robinson's letter, for they will find therein many arguments which will readily convince them of the Council's wisdom. He says: "Forty-five years ago the scheme would have been a benefit to the profession." That would have been in 1880—many years before any of the defence societies had started on their successful and prosperous careers leading to the accumulation of large reserve funds. In spite of the existence of three defence societies with large reserve funds, I cannot see how he can assert that what would have been right in 1880 is wrong in 1925, seeing there are a very large number of practitioners still without medical defence. If the existence of three defence societies in 1925 makes all the difference, the addition of a fourth would still be in the right direction, especially as he predicts that the fourth will be eventually outside the control of the Association. One cannot have too much of a good thing. For then there would be four offices (I include the Scottish Defence Society), four councils, four paid secretaries, four auditors, four advertisement accounts, and all to be paid for by the struggling practitioner, who would be privileged by the protection afforded by "managers highly experienced in the work of individual defence."

Dr. Henry Robinson is one of these managers: he is a member of the council of the Medical Defence Union. As such one would have thought that he would have been more conversant with the history of individual defence than to assert, "When these societies came into existence many years ago, there was, I gather, no desire on the part of the British Medical Association to undertake individual medical defence." As a matter of history (too long to detail here) it was the desire of the members of the Association to start individual defence, but they were always hampered in their efforts by the legal constitution of the Association. I have no doubt (although I have no evidence at hand to prove this) that it was those very members of the Association who desired it to undertake individual defence who founded the present-day defence societies. In a sense these are but sports of the parent body, not a new or distinct species of organization.

Dr. Robinson's criticism of the Council's recommendation to the Representative Body is full of possibilities that are not likely to happen. The suggested separate organization in close relation to the Association, to carry on individual defence, seems to be quite feasible, and I have no doubt that the legal experts in company law can make the separate organization in such close relation to the Association as to be virtually under its control. When well established it may be possible to alter the Memorandum of Association so as to make the new society part and parcel of the Association. In any case, whether or no, this is the day of associated companies and amalgamations.

As regards finance, it is quite true, as Dr. Robinson states, that the Association funds cannot be used to support the "company"; but he admits that the present companies for defence started from zero, and are now wealthy companies with large reserve funds. Why cannot the proposed "company" have equal success, especially as it will commence its career equipped with a self-starter in the shape of the British Medical Association, which will help it to get off from the zero mark with great celerity?

Dr. Robinson makes a great point that the British Medical Association must disclose to the newly qualified innocents that the new company has no reserve funds, while the older companies "have funds running into thousands of pounds." I quite agree with him, and I think the Association should go further, and tell the newly-qualified how profitable the business is, and the number of thousands these companies have in reserve. Probably these amount to about £60,000 to £70,000, and their combined annual income cannot be less than £20,000. The Association should

also inform the newly qualified that, taking the Medical Defence Union as an example, it paid to the Yorkshire Insurance Company in 1922 £1,280 3s. 9d. to insure its 9,375 members. This works out at 2s. 9d. a head.

If the new "company" is started and is well supported from the first (though I believe it will take some time to get 6,500 members), there is no reason why funds should not accumulate as they have done in the older societies. When the funds reach the maximum needed for safe cover, then either the premium can be reduced or the surplus money can be used for the benevolent purposes of the Association, or otherwise as the proper authority may direct.

The new "company" will have a great advantage over the older companies in that it will be able to have office accommodation in the Association's new house in Tavistock Square. This, no doubt, would be let free or at a nominal rental. By this convenience, and by close relationship with the Association and its staff, overhead and establishment charges could be kept low.

Dr. Robinson states that there is extraordinarily little dissatisfaction among 20,000 odd members of the defence societies, by whom, directly or indirectly, the entire councils are elected. This only goes to show that there is very little happening in connexion with the defence societies. As a matter of experience I find that men pay their annual premium and very soon forget the name of the company they are insured with. This indifference will be changed to active interest when they insure with the British Medical Association company.

One real difficulty about the defence question Dr. Robinson does not touch upon. That difficulty concerns breaches of professional conduct and practice such as might be brought before the General Medical Council. I should like to ask Dr. Robinson, as an experienced manager and member of council of the Medical Defence Union, whether his company would prosecute a member of his company before the General Medical Council for advertising, touting, or other grave professional offence affecting the honour of the profession. The question of the self-discipline of the profession must be considered in its relation to individual defence against charges made by the laity. Personally, I think this duty will be discharged better by a strong British Medical Association society than by a number of other societies all competing for members.—I am, etc.,

Warrington, April 26th.

J. S. MANSON.

## THE ROYAL ARMY MEDICAL CORPS.

SIR,—In the SUPPLEMENT to the JOURNAL, January 3rd, 1925 (p. 10), is a note of the proceedings of the Naval and Military Committee of the British Medical Association. Sir Richard Luce said that the position of the R.A.M.C. was becoming worse owing to the shortage of candidates. Seniors were doing the work of juniors. There was a block in promotion. A higher rate of commencing pay should be offered. Sir William Macpherson thought that the Association should use its influence with medical schools to encourage entrance to the R.A.M.C.

In the JOURNAL of April 11th (p. 709) your article upon the pensions of R.A.M.C. officers makes very clear the financial position. It is well worth study by those who contemplate joining the corps. It is well that candidates should realize what has always been understood—namely, that no contract made by the War Office with officers will hold good for a single day if the War Office thinks fit to repudiate it.

During the years 1878 and 1879 there was similar difficulty in obtaining candidates. I am a Bart's man, and I well remember the surprise and regret of the late Sir Norman Moore, then our dean, when I expressed my intention of joining the Army Medical Service. The Royal Warrant of 1879 was seemingly very attractive. It gave newly joined officers £1 per diem, plus allowances that came to about £90 yearly, say in all some £450 per annum. But within a year the majority of those who sat for examination in 1879 (including Sir Alfred Keogh, myself, and some eighty others) were sent to India, where we found our pay and allowances included came to a total of only £317 per

annum. No young officer—or candidate—reads a Warrant with much understanding. We had not noticed a simple sentence that this Warrant did not apply to India, or considered exactly what it meant. However, we knew later. The position had been camouflaged, and we were caught in the toils of the hunter.

Sir William Macpherson's idea is beautiful and simple. The War Office is short by, I believe, some sixty officers, and not only the twenty asked for, and these sixty officers' work is thrust upon others. Surely the medical schools might well come forward and allay the discontent! I am reminded of a similar suggestion made a few years ago, when the I.M.S. were being broken on the wheel. This was that the R.A.M.C. should amalgamate with them. One can imagine the Adjutant-General, now the real chief of the Army Medical Service, smiling to himself ironically, and devising fresh forms of birdlime.

The R.A.M.C. rests upon too slender a basis at present. The corps has three pressing needs:

1. The D.G. should be upon the Army Council, where he can plainly and personally express the disabilities of his service and also set forth the needs of the army itself, in a way that no Adjutant-General is, or ever will be, capable of doing.

2. The financial contract should be regarded as inviolable, with this addendum that when a new Royal Warrant is promulgated all serving officers should have the option of transfer to the new terms if they prefer them.

3. Directors-General should be chosen from those senior and experienced officers who have borne the heat and toil of long service, whose right and claim it is to occupy the position, and who know the army from top to bottom. But possibly the War Office does not desire that the D.G. should know too much. A hard man with wide experience is a difficult nut to crack.

My experience and observation—extended now to forty-five years—is that the army has been splendidly served by my old corps, and by the medical profession, during the late war; and it is not too much to say that without the highly trained officers of the present day the British Army would fall to pieces. I will not argue this point, but those who know the multifarious duties of the Royal Army Medical Corps are well aware that it is so. And those who understand the constitution and the lines of thought in the army also know that the three points I have specially dealt with are essential in order that the corps may perform its external duties efficiently, while internally the officers of all ranks are satisfied and contented. It is not enough to flatter and make much of the corps in the strenuous days of war and to ignore obvious needs in times of peace.

I fear I cannot entirely agree with Sir Richard Luce and his committee that a high rate of pay upon joining should be offered. This makes it too easy for the subaltern to marry, and he is thus dissociated from regimental life and discipline, which is so different from that of the medical student. In my opinion the newcomer, if married, rarely becomes as efficient an officer of the army as does one who has served some six to ten years intimately appreciating the ideas current in a regiment, and incidentally learning something of his own character. Far better is it for an officer to know that his future prospects and financial position are guarded and guaranteed when eventually he takes the step against which *Punch* warned all men long ago.

I have touched upon salient points in the merest outline. All are capable of expansion in argument. But I should like to add that just as it always was, and always will be, the duty of every senior officer on the active list to uphold and support his juniors, as does every regimental colonel, so also when an officer retires he should endeavour to act upon the same principle and should press the adoption of measures that will consolidate the position of the corps. And I urge that this is also a national duty, perhaps the only one that such an officer is able to assist in.

Sir Richard Luce's committee has thus carried out loyal and valuable service in addressing the War Office. It would be interesting to see the full memorandum in print, and the reply.—I am, etc.,

Junior United Service Club,  
April 22nd.

T. M. CORKER,  
Major-General.

## MEDICAL MEMENTOOS.

SIR,—With this I send you a pamphlet describing the contents of a unique cabinet of medical mementoes of five persons of supreme influence on medicine: Benjamin Rush, Edward Jenner, Joseph Lister, Louis Pasteur, and Marie Curie, two of them, Pasteur and Mme Curie, not being doctors.

This cabinet of memorabilia was a gift from Dr. Robert Abbe of New York to the College of Physicians of Philadelphia, which was founded in 1787, and is the oldest medical body in America. Our new building is fireproof, and our library is only excelled in America by that of the Surgeon-General of the United States Army in Washington.

Dr. Abbe appointed Dr. S. Weir Mitchell the first custodian; he passed it on to Dr. Simon Flexner of New York, he to Dr. William H. Welch of Baltimore, and he, in 1924, to myself. I have filed with the College of Physicians the name of my successor, in a sealed envelope.

The contents of the cabinet are the shoe buckles and watch of Rush; the inkstand used by Jenner, and a lock of his hair; a case of instruments used by Lister, and the test tubes of sterilized milk, now evaporated to dryness, but which, though exposed to the air, never underwent putrefaction in many years; the pasteboard model of a crystal of tartaric acid, made, labelled, and used in his lectures by Pasteur—the gift of Dr. Calmette of the Pasteur Institute; and finally, the instrument used by Professor Pierre Curie and Mme Curie, in their earliest investigations of radium, just after her discovery of radium, and presented by Mme Curie herself. This will give a good idea of the character of the contents of this unique cabinet.

There are three pre-eminent names not yet represented in this collection, and I am in diligent search of some object touched or used by them—if any such objects can be found: William Harvey in England, and Vesalius and Ambroise Paré on the Continent. If by any possibility any of your readers, British or Continental, can give me any information leading to obtaining such objects, I shall be infinitely obliged.—I am, etc.,

W. W. KEEN, M.D.,  
Hon. F.R.C.S. (Eng., Edin., and Ire.)

1520, Spruce Street,  
Philadelphia, April 15th.

\*\* The well printed pamphlet forwarded by Dr. Keen, with its beautiful illustrations, is in itself a medical memento of considerable interest. We wish him good fortune in his pious quest.

## Obituary.

SIR ARTHUR WILLIAM MAY, K.C.B., F.R.C.S.,  
Surgeon Vice-Admiral, R.N.(ret.); late Medical Director-General,  
Medical Department of the Navy; Honorary  
Physician to the King.

We announced briefly in our last issue the death, on April 20th, of Surgeon Vice-Admiral Sir Arthur May at his Cornish home, where he had lived since retiring from the post of Medical Director-General R.N.

Arthur William May was born on June 18th, 1854; his father was the Rev. H. T. May, Fellow of New College Oxford. From Sherborne School he went to King's College Hospital, London, and obtained the diplomas of M.R.C.S. in 1876 and L.R.C.P. in 1877. In 1914 he was elected Fellow of the Royal College of Surgeons of England.

He entered the Royal Naval Medical Service in 1878, he served during the Egyptian war of 1882 in H.M.S. *Achilles*, receiving the medal and the Khedive's bronze star. Two years later he took part in the Suakin expedition and the Nile expedition for the relief of General Gordon at Khartoum, and was mentioned in dispatches for his attention to wounded under fire. He was promoted staff surgeon in 1890, and fleet surgeon in 1898. From 1901 to 1904 he was principal medical officer in H.M.S. *Britannia*, and from 1905 to 1909 he served as deputy director-general of the medical department of the navy. After serving as medical officer in charge of the Royal Naval Hospital, Chatham, he

was appointed in May, 1913, to succeed Sir James Porter at the Admiralty as medical director-general, with the rank of surgeon vice-admiral. Thus he was head of the Royal Naval Medical Service at the outbreak of war, and remained in charge of the department until his retirement in June, 1917. He received the C.B. in 1911 and was promoted K.C.B. in 1914.

For the following appreciation we are indebted to Sir Humphry Rolleston, Bt., K.C.B., P.R.C.P., consulting physician to the Royal Navy:

Surgeon Vice-Admiral Sir Arthur William May, K.C.B., K.H.P., had a distinguished war service, and in 1913, after being deputy director-general of the medical department of the Admiralty, and then medical officer in charge of the Royal Naval Hospital, Chatham, he succeeded Sir James Porter as director-general, and so was responsible for the Naval Medical Service during the war until June, 1917. His term of office then came to an end, and, though not to continue his unsparring labours until the armistice must have been a disappointment, no outward sign of this was allowed to appear. His services were great, and have hardly received their due recognition, partly, no doubt, because of the relatively small personnel of the navy as compared with that of the army. The good bill of health of the navy owes much to his constant supervision: he was, of course, responsible for the very prompt and considerable expansion of the Naval Medical Service by the enrolment of temporary surgeons R.N. and the calling up of surgeons R.N.V.R., as well as for the commissioning of hospital ships and other emergency measures. A far-seeing man, he was anxious to do all he could for the good of his service by taking outside advice, and gave most loyal support to the civilian consultants. When cerebro-spinal fever broke out early in 1915 he took great trouble in formulating measures to obviate its spread, and continued to supervise the Admiralty orders, and, as new knowledge was obtained, modified them accordingly. Most conscientious, hard-working, and rather highly strung, he suffered in health from inability to save himself labour by delegating work and in other legitimate ways. With such a high standard he naturally expected much from his subordinates, and thus had the reputation of being rather a stern master. When I was his subordinate he was always most considerate and kind. After his retirement he lived at Tremecr, St. Tudy, Cornwall, and was extremely energetic in organizing Red Cross and other activities, as well as being deputy lieutenant and justice of the peace for the county. An athlete in his younger days, and always a keen sportsman, it must have been a sad trial to be laid aside by a hemiplegic attack a year ago.

Sir JAMES PORTER, K.C.B., K.C.M.G., Sir Arthur May's predecessor in the office of Medical Director-General R.N., sends us the following tribute:

I have been asked to write a brief personal appreciation of Sir Arthur May. I knew him well. In our days of active service our personal experiences of each other were well-nigh unique. When I was M.D.G. he served under me as D.M.D.G. When the great war came and I was recalled to service I served for over three years under him. Although in many ways we were men with a different outlook on life, yet we were always at one when vital service interests were at stake, in spite of the possible points of contact being numerous and not infrequently cropping up. During these long years of intimate official relations no angry word ever passed between us. I endorse all that Sir Humphry Rolleston has so well expressed. Sir Arthur outworked his strength, and so eventually by his own act and deed he compassed his end. His ardent nature and deep sense of duty led him to follow too far the specious maxim, "If you want a thing well done you should do it yourself, you should not leave it to others." Devoted to his profession, his knowledge of it was profound, extensive, and always kept abreast of the times. On entry to the Navy he obtained first place in his batch, and from that moment he never looked back. As M.D.G. his delight was to enter and encourage young surgeons of the best stamp, only the best being good enough for our invaluable seamen. For the "dry rot"

which has so disastrously attacked the medical service since May left in 1917 he can be held in no way responsible. Never a seeker of popularity, it is true he did not "suffer fools gladly." Towards the end of his active service, ill health increased the difficulties of a position which, if properly maintained, cannot be free from troubles. Sir Arthur May was an upright man, straight in all his dealings. His King and country never had a more faithful or devoted servant. Official honours are notoriously not exactly showered upon naval medical officers. Hence, presumably, it happened that neither May's gallant conduct in the *Sofa* before Khartoum in January, 1885, nor his hard administrative labours during the first three years of the great war received any recognition. No matter—"The prize he sought and won was the crown for duty done."

#### ROBERT J. M. BUCHANAN, M.D., F.R.C.P.,

Consulting Physician, Royal Infirmary, Liverpool; late Professor of Forensic Medicine, University of Liverpool.

THE death of Dr. R. J. M. Buchanan, which we announced in our last issue, came as a great shock to his numerous friends and patients in the city of Liverpool, and regret was universally felt at the sad loss the profession has sustained. He was taken suddenly ill with pneumonia, and passed away, within a week, on April 19th.

Dr. Buchanan's life is a striking example of consistent diligence and perseverance in surmounting difficulties and finally attaining an honoured position in his profession. As a medical student he had a distinguished record. He obtained the M.R.C.S., L.R.C.P. diplomas, and the M.B., Ch.B. degrees in 1888 with honours in systematic and clinical medicine at the Victoria University of Manchester, to which the University College of Liverpool at that time was affiliated. The following year he became M.D. and received the gold medal for his thesis. In 1897 he became M.R.C.P. Lond., and in 1908 was elected a Fellow. A strenuous worker and painstaking clinician, Dr. Buchanan, early in his career, was appointed physician to the Stanley Hospital. He also held the post of honorary physician to the Hospital for Consumption and Diseases of the Chest. Pathology was a great source of inspiration in his clinical work, and he held the post of assistant pathologist in the University, where his demonstrations were much sought after by the students, who appreciated the untiring efforts of their teacher. It was a natural consequence that Dr. Buchanan should pass on to the staff of the Royal Infirmary, where he became first assistant physician and then full physician. His retirement only last December was due to the age limit, and he was elected as honorary consulting physician.

Dr. Buchanan was an able and methodic teacher; many medical students now practitioners will call to mind affectionate memories of the man and his manner. In the University he occupied the chair of forensic medicine, which he only recently relinquished. His lectures were lucid and practical, and these were made interesting, and even entertaining, by his innate ability in word-painting. His textbook of forensic medicine and toxicology was essentially practical, and furnished without over-elaboration the information in medico-legal subjects the general practitioner should possess. As a member of the Liverpool Medical Institution he held various offices, and was a vice-president in 1914. As a speaker he was brief and to the point, and in discussions he was wont to emphasize some view that might not have occurred to others. His papers on rabies and hydrophobia, on blood in health and disease, revealed much careful research, and set forth his views in no uncertain language. He was ever ready to avail himself of the most recent advances in pathology, and especially its bearing on therapeutics. Toxaemic conditions loomed largely in his outlook on disease, and he may at times have been induced to lay too much stress on these in the application of therapeutic measures.

In the great war Dr. Buchanan served as captain, R.A.M.C., and was on the staff of the 1st General Western Hospital at Fazakerley. He took great interest in the production of gas in chemical warfare and was in

frequent communication with the authorities on this subject. Some five years ago he lost his elder son after a long, lingering illness. The young man had been through the war, and was a medical student when he died. This was a great blow to his father; indeed, Dr. Buchanan was not the same man, and there is no doubt that his health suffered in consequence of his great grief.

Dr. Buchanan was a man of many parts. He was an artist of no mean order, and chiefly excelled in landscape painting. Many of his pictures have been hung in the local exhibitions. A good teller of stories, his company was ever welcome, and laughter was a frequent accompaniment that he was present and that he was the cause of it. He was fond of angling and enjoyed the solitude this recreation brings with it. He loved music and was fond of translating his auditory impressions into visual ones; he would describe a Wagnerian masterpiece in tones of colour. He was a lovable man; his artistic temperament readily responded to his surroundings; to strangers he might appear to be somewhat gauche, but once this impression passed the intellectual ability of the man stood out distinctly, and his fellow practitioners recognized his professional worth.

A memorial service was held in the Lady Chapel of Liverpool Cathedral on April 23rd, when many of his professional brethren and friends attended to pay their last respects to a man whom they will ever hold in affectionate remembrance. Dr. Buchanan leaves a widow and a younger son, with whom sincere sympathy is felt in the loss of one who had earned the affectionate regard of so many with whom he came into contact.

#### JAMES DON, M.D., C.M.ABERD.

Senior Surgeon, Newcastle-on-Tyne Throat and Ear Hospital.

On April 23rd the medical profession in Newcastle and the North of England learnt with deep regret and sorrow of the death of their colleague Dr. James Don, at the age of 61. It appears that he was infected by a patient who coughed in his face during a consultation; he developed phlegmonous pharyngitis, from which he died.

James Don was a native of Aberdeenshire, and studied medicine at the University of Aberdeen, graduating M.B. and C.M. in 1888, and proceeding M.D. with honours in 1890. He went to Newcastle-on-Tyne in 1892, and remained in general practice there until four years ago, when he devoted himself entirely to throat and ear work. He was surgeon to the Newcastle Throat and Ear Hospital for thirty years, and senior surgeon at the time of his death. He was also aural surgeon to the War Pensions Hospital, Castle Leazes, near Newcastle.

Dr. Don was for many years a whole-hearted worker for the British Medical Association in the interests of his brother practitioners. He became a member of the Newcastle Division soon after beginning practice there, and was chairman of the Division in 1912 and 1924, deputy representative from 1913 to 1916, and representative from 1917 to 1921; for the past thirteen years he had been a member of the North of England Branch Council; he was honorary secretary of the Branch from 1915 to 1924, and at the time of his death was president-elect. He had been a member of the Central Council of the Association since 1920, and of the Central Ethical Committee since 1921. The Annual Meeting at Aberdeen, in the week before the outbreak of war, was a great pleasure to him, for he delighted in conducting fellow representatives round his Alma Mater. He was a member of the Arrangements Committee for the successful Annual Meeting at Newcastle in 1921, and served as vice-president of the Section of Oto-Rhino-Laryngology. This brief outline of the offices held by Dr. Don in the British Medical Association does not, however, complete the record of his services to the profession. He had worked hard as chairman of the local Division during the critical time when the National Insurance Bill was before Parliament; when the provisional local Panel Committee was formed he was elected its chairman; and in later years he continued to serve on the Newcastle-on-Tyne Panel Committee. Throughout the war he performed the duties of secretary of the Local Medical

War Committee without friction, and served as surgeon to the Pendower V.A.D. Hospital. At the time of his death he was vice-chairman of the Newcastle Medical Institute and an active member of the Newcastle and Northern Counties Medical Society.

A colleague and friend, to whom we are indebted for the particulars given above, writes:

"James Don spoke ill of no one and had a charitable outlook on life. He was very cautious, and sometimes it took a good deal of trouble to convince him, but once convinced of the rightness of a course he was an ardent and loyal supporter. I have seldom known a death cause such consternation and universal regret. He was a fine man, and he will be sadly missed."

The funeral was a most striking testimony to the regard in which Dr. Don was held; it was attended by many influential people of all classes and very largely by representatives of the profession all round Newcastle. The Council of the British Medical Association was represented by its Chairman, Dr. R. A. Bolam.

#### REGINALD DUDFIELD, O.B.E., M.A.CANTAB., M.B., D.P.H.,

Medical Officer of Health, Paddington.

We greatly regret to have to record the death, in London on April 19th, of Dr. Reginald Dudfield, medical officer of health for the metropolitan borough of Paddington. He had occupied that position for over thirty years, partly indeed in the days of the vestry before the borough was created. Dr. Dudfield was an outstanding figure in the ranks of those whose life is devoted to the promotion of public health and the prevention of disease. He was a thoroughly competent business man who carried out efficiently every responsibility he undertook. His father before him, Dr. Orme Dudfield, occupied a similar position for the borough of Kensington, and was a man of the same high standing. Dr. Reginald Dudfield, after a successful university career and a period of office as medical officer of health for Eastbourne, was appointed to Paddington, but his energies were by no means confined to the direct service of his local authority. He was a vice-president and honorary foreign secretary of the Royal Statistical Society and at the time of his death had been for some years honorary secretary to the Section of Epidemiology of the Royal Society of Medicine. He had also been president of the Harveian Society. His work included valuable service during the war, in connexion with which his name was mentioned in dispatches. His literary labours included a period of editorship of *Public Health*, and he was the author of a history of the Society of Medical Officers of Health. He gave much attention to the value of statistical data, and he contributed to the *Journal of the Royal Statistical Society* an important article on the methods of recording and publishing statistics. During the existence of the Vaccination League, which was established under the secretaryship of the late Mrs. Garrett Anderson, he took a prominent part in the efforts then made to have primary vaccination and revaccination placed on the same legal basis, as being equally important in the protection of the public against small-pox. At the time of his death he was 64 years of age, and had been looking forward to retirement from office to afford him a period of leisure during which he could work up some of the material, especially statistical, which pressure of official duty had prevented him from completing. It is a melancholy coincidence that just a year ago Dr. Richard Reece died suddenly at about the same time of life, and so was cut off also from the realization of a leisured retirement. The two were colleagues in the same Section of the Royal Society of Medicine—the latter as president, the other as secretary. Dr. Dudfield's death occurred some days after an operation for appendicitis.

A funeral service took place on April 21st at St. Mary's Church, Paddington Green, close to the Town Hall in which Dr. Dudfield had for so many years done his daily work. The attendance, both in numbers and composition, indicated the high esteem in which he had been held by his council and colleagues. After the service cremation

was carried out at Golders Green. The greatest sympathy is felt for his widow and family by all who had any knowledge of the part Dr. Dudfield took, not only in the administration of Paddington, but in the general advancement of public health.

#### ARTHUR JOSEPH EAGLETON, M.D., M.R.C.P.

THE many friends of Dr. Arthur Joseph Eagleton will regret to hear of his death recently at Newark, U.S.A., at the early age of 34.

Dr. Eagleton went from Rugby to Guy's Hospital. He became pathological assistant to the surgical registrar in 1913, and was awarded the Golding-Bird gold medal for bacteriology. While holding a house appointment he volunteered on the first day of the war, and received a commission a few days later, when he went to France. He became bacteriologist to the 3rd General Hospital (B.E.F.), and was also in the 15th Field Ambulance. Later he became a cerebro-spinal fever specialist in one area of England, and published an article on the occurrence of meningococci in the air of army huts. After the war he took charge of the bacteriological department of the Wellcome Physiological Research Laboratories, where he remained until 1923, when, finding it necessary to avoid the winter in England, he went as bacteriologist to the Eye and Ear Hospital at Newark, U.S.A. Prior to his departure he had been secretary to the Pathological Section of the Royal Society of Medicine. He published several papers giving the results of his careful investigations into methods of standardization of tuberculin, on the Schick test and active immunization against diphtheria, and into the virulence of diphtheria bacilli. A colleague writes: "His work, particularly in connexion with the standardization of tuberculin and the virulence of diphtheria bacilli, had already placed him amongst the most promising of the younger group of pathologists. In America he had commenced a lengthy series of well planned observations and experiments on the diagnosis and treatment of ophthalmic tuberculous conditions and on protein sensitization, and had carried the investigation far, despite the handicap of ill health. His premature death deprives pathology of a keen worker of careful judgement, who promised to make further contributions of great value to bacteriology. His unselfish kindness, sincerity, and his high personal ideals gained him the affectionate regard of his colleagues and of those who worked under him. He will be missed by a large circle of friends."

#### THE LATE SIR RICKMAN GODLEE.

THE funeral of Sir Rickman Godlee at Whitechurch, Oxon, was attended by Sir John Bland-Sutton, President of the Royal College of Surgeons; Sir John Rose Bradford, Professor W. F. Oliver, Professor R. W. Chambers, and Professor G. Elliot Smith, representing the University of London and University College; Sir George Blacker, representing University College Hospital and Medical School; Sir George Newman (Ministry of Health), and Mr. F. G. Hallett, representing the Conjoint Board of the Royal Colleges of Physicians and Surgeons. Lady Godlee has received a message of condolence from the King, recalling the fact that Sir Rickman Godlee had been a member of the King's Household in this and previous reigns, and expressing His Majesty's sympathy with Lady Godlee in her loss. Sir Rickman Godlee was a member of the Central Medical War Committee. He joined it in August, 1915, when it was known as the War Emergency Committee, and continued to serve until it was dissolved. He was assiduous in his attendance, and did much good work in keeping the committee in touch with the staffs of hospitals and medical schools. He also acted as chairman of one of the sections hearing appeals.

We are indebted to Mr. G. GREY TURNER of Newcastle-on-Tyne for the following note:

"The writer of your interesting obituary notice of Sir Rickman Godlee has omitted to mention his association with the American College of Surgeons. While president of our own College he crossed the Atlantic to attend the first Con-

vocation of the new American College, which was held in the Congress Hotel in Chicago on November 12th, 1913, under the presidency of Dr. J. M. T. Finney of Baltimore. On that occasion Sir Rickman conveyed a message of greeting from our Royal College, and also delivered the first Fellowship Address. In the latter he sketched the history of surgery in England up to the formation of the College of Surgeons in 1800, and followed its destinies to the time of its incorporation as a Royal College in 1843. He also dealt with its various activities, and especially as an examining body and as the custodian of the Hunterian Museum. The tone of helpful friendship which he adopted made a great impression, and altogether his visit did much to arouse those feelings of mutual good fellowship which were before long to be cemented on the battlefields of Europe, and which were consummated, so to speak, by the gift of the 'Great Mace' to the American College from the consulting surgeons of the British armies. At this Convocation he was invested with the Honorary Fellowship of the American College, which was conferred upon him in company with Halsted of Baltimore, Keen of Philadelphia, Collins Warren of Boston, and Weir of New York, who together formed the first batch of Honorary Fellows. At the same Convocation ordinary Fellowships were granted to no fewer than 1,059 candidates. His visit will not soon be forgotten on the other side, and there are many surgeons in America who will mourn, not only the loss of a great figure, but that of a firm friend."

By the death of Dr. EVAN PRICHARD Banbury and the neighbourhood loses an able practitioner and his patients a good friend. He received his medical education at Edinburgh University, and graduated M.B., Ch.B. in 1902, proceeding M.D. in 1906. His first appointments were assistant resident medical officer to the Edinburgh City Poor Hospital, and house-surgeon to the Gloucester General Infirmary and Eye Institute. Prichard was one of those men to whom a patient's illness and troubles were his own anxiety throughout, and if a patient wanted him he could not rest until he had been to see him. His patients gratefully recognized this, for when, a little more than a year ago, he had a serious attack of streptococcal septicaemia, the bulletins on the door of his house were watched anxiously by all classes of his patients. He engaged in all branches of practice, and where he felt himself deficient he did not hesitate to say so and to seek further help. But it was as a surgeon that he did his best work; at the Horton Infirmary, Banbury, he was prepared to do, and did well, all the ordinary major operations. Nor was he deficient in that essential quality of a good surgeon, the ability to do the right thing in an emergency. In his dealings with his fellow practitioners his most lovable characteristic was his boyishness, his open heart, his cheerful and direct speech. It is with feelings of great regret that his colleagues in the Oxford Division of the British Medical Association look upon his untimely death, when much of his life's work lay in front of him. A fund has been opened to provide a memorial at the Horton Infirmary, with which Prichard had been associated since he went to Banbury in 1907. He is survived by his widow, three sons, and one daughter.

#### The Services.

##### DEATHS IN THE SERVICES.

Major-General Sir Richard William Ford, K.C.M.G., C.B., D.S.O., Army Medical Staff (retired), died at Mentone on March 31st, aged 67. He was the son of Richard William Ford, clerk of the peace, Portsmouth, and was educated at Sherborne School. After taking the M.R.C.S. in 1879, and the L.R.C.P.Ed. in 1880, he entered the army as surgeon in 1881, became colonel in 1909, and, after thirteen months on half-pay, from January 26th, 1913, to March 6th, 1914, was promoted to surgeon-general on June 1st, 1914. He had seen much active service, beginning with the Egyptian war of 1882, when he received the medal and the Khedive's bronze star. In the South African war he served from 1899 to 1901, taking part in operations in the Orange River Colony, including the ten days' operations at Paardeberg, and the actions at Poplar Grove, Driefontein, Vet River, and Zand River, also in operations in the Transvaal, and took part in the relief of Kimberley; was mentioned in dispatches in the *London Gazette* of April 16th, 1901, and received the Queen's medal with four clasps, and the D.S.O. After the war he was seconded for five years for service as deputy surgeon of the Royal Hospital, Chelsea. On promotion to major-general he became D.M.S. of the Northern Command. After the war began he was appointed D.M.S. in Egypt, holding that appointment from 1914 to 1916, when he became D.M.S. in Ireland (1916-18). He was again mentioned in dispatches in the *London Gazette* of

MR. BASIL GRAVES, who in 1922 was appointed a British Medical Association research scholar to investigate methods of illumination of the eye for clinical examination and of microscopy of the living eye by the Gullstrand slit lamp and the eye microscope, as well as the examination of the fundus by the Gullstrand ophthalmoscope, has continued his inquiries, and was invited to open a discussion on the microscopy of the living eye at the Annual Meeting at Bradford last year (BRITISH MEDICAL JOURNAL, October 25th, p. 756). Since the beginning of this year he has been giving courses on ocular illumination and illumination in the department of the Graduate School of Medicine of the University of Pennsylvania, Philadelphia. He has given six such courses, each limited to six persons. A course consisted of a lecture of one hour and practice for one hour and a half daily for five days a week for two weeks. The demand was so considerable that many more courses than were originally arranged had to be given. Mr. Graves has also delivered the Rush Lecture before the College of Physicians of Philadelphia, and introduced a discussion on the slit lamp for ophthalmic surgical practice at the meeting of the Pennsylvania Section of the American College of Surgeons last March.

At the Bedfordshire Quarter Sessions, on April 8th, the new magistrates who took the oath included Dr. A. E. Street (Cranfield) and Dr. P. T. H. Steadman (Leighton Buzzard).

DR. LLOYD W. HUGHES of Bottwog, Pwllheli, has been returned unopposed to the Carnarvonshire County Council.

DR. A. G. TOLPITT has been elected chairman of the Kettering Urban District Council.

THE first centenary of the foundation of the Oporto faculty of medicine will be celebrated from June 22nd to 27th.

THE next meetings of the Royal Commission on Lunacy and Mental Disorder will be held at 5, Old Palace Yard, Westminster, on Monday and Tuesday, May 4th and 5th, beginning at 10.30 a.m. each day.

A LIST of maternity and child welfare centres in England has been published by the Ministry of Health, and may be obtained from H.M. Stationery Office (price 1s. 6d.). The list includes all municipal and voluntary maternity and child welfare centres known to the Ministry of Health in March, 1925, the centres being grouped in three sections: (1) London, (2) county boroughs, (3) counties, in this last case the centres being classified according to sanitary districts.

DR. CABANES, the well known medical historian and editor of the *Chronique médicale*, has recently received the Cross of the Legion of Honour.

THE issue of *Paris médical* for April 4th contains an illustrated review of the fifth Salon des médecins organized by Dr. Paul Rahier, whose genial personality is reproduced in a sketch by M. Tahindjis. Other exhibits of medical interest are a portrait of the late Professor Paul Séguin by Mme Fournau-Séguin, a medallion of Claude Bernard by Professor Hagen, and a bust of Professor Léon Bernard by Mme Bécéc Vautier.

DR. AUGUSTE PETIT of the Institut Pasteur, who is well known for his work on spirochaetosis, icterohaemorrhagica, has been elected a member of the Académie de Médecine in place of the late Dr. Jean Camus.

THE first Latin-American Congress of Medicine will be held in Paris in June, 1926, under the presidency of Professor Roger, dean of the faculty of medicine.

THE Queen of the Belgians has been presented with the gold medal of hygiene by the French Republic.

ON May 16th and 17th the first Polish Antituberculosis Congress, and on May 18th and 19th the fourth Congress of Polish Physicians and Sanitary Town Officials, will be held in Cracow. The principal subjects to be dealt with in the Antituberculosis Congress are: (a) clinical classification; (b) specific and surgical treatment; (c) treatment by artificial pneumothorax; (d) climatological and sanatorium treatment; (e) the importance of dispensaries; (f) organization in Poland of the antituberculosis campaign. The principal subjects to be considered at the Sanitary Congress are: (a) school hygiene; (b) the protection of mothers and children from the standpoint of sanitation; (c) the campaign against child mortality.

THE late Mr. Thomas Hamer of Tyldesley has bequeathed £1,000 to the Manchester Royal Infirmary, £500 each to the Manchester Royal Eye Hospital, the Southport Convalescent Home, the Leigh Infirmary, the Wigan Infirmary, the Bolton Infirmary, and the Devonshire Hospital, Buxton, and £250 to the Royal Manchester Children's Hospital, Pendlebury.

A NEW medical society has been founded at Amsterdam under the name of Het Amsterdamsche Geneeskundig Genootschap.

HUXLEY was born on May 4th, 1825. The issue of *Nature* for May 9th will include a special supplement, to which a number of leading authorities on biological evolution will contribute; among them are Sir E. Ray Lankester, Sir Arthur Keith, Professor MacBride, Sir W. T. Thiselton-Dyer, Sir Arthur Smith Woodward, and Professor Arthur Thomson.

THE Belgian Society of Stomatology will celebrate its twenty-fifth anniversary in July.

THE report of the First International Congress of Open-Air Schools, held in Paris, in June, 1922, which has now been published, contains an account of the various discussions and resolutions adopted, with especial relation to technical details and the general benefits of this form of education, which is rapidly gaining favour in France. The delay in publication is ascribed to the necessity for obtaining a report accurate in every detail. It is published by Messrs. Maloine of Paris at the price of 10 francs.

THE late Sir T. Clifford Allbutt, P.C., K.C.B., F.R.S., Regius Professor of Physic in the University of Cambridge, and President of the British Medical Association 1915-21, who died in February last aged 88, has left estate of the gross value of £56,963, with net personalty £50,137. He bequeathed to the Fitzwilliam Museum, Cambridge, his portrait by Sir William Orpen, R.A., and on the death of his wife a quantity of antique furniture and drawings and paintings by noted artists, including Rembrandt, Landseer, Rossetti, Watts, and Turner. To Gonville and Caius College, Cambridge (of which he was a Fellow), he gave three silver and gilt drinking horns or cups, requesting that his name as donor should be engraved thereon. Subject to the fulfilment of personal bequests and life interests, and the failure of issue, the ultimate residue of his property is bequeathed to Gonville and Caius College for Clifford Allbutt Fellowships for medical research, or otherwise for the benefit of the college, provided that no part thereof be used for building.

## Letters, Notes, and Answers.

ALL communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, 429, Strand, W.C.2.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Matter intended for the current issue should be posted so as to arrive by the first post on Monday, though in special circumstances urgent communications can usually be received on Tuesday morning.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, 429, Strand, W.C.2, on receipt of proof.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager, 429, Strand, W.C.2. Attention to this request will avoid delay.

THE TELEPHONE NUMBER of the **BRITISH MEDICAL ASSOCIATION** and **BRITISH MEDICAL JOURNAL** is **GERRARD 2630** (Internal Exchange).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Antiology Westrand, London.*

FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate Westrand, London.*

MEDICAL SECRETARY, *Mediscera Westrand, London.*

The address of the Irish Office of the **British Medical Association** is 16, South Frederick Street, Dublin (telegrams: *Haecillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### ANOSMIA.

"A patient, aged 60, with treatment of a man, aged 60, with anosmia of the nose and throat, who has completely lost his sense of smell for two months, following an ordinary 'influenzal cold.'"

### INCOME TAX.

#### Motor Car Transaction.

"W. M." bought a new car in 1912 for £550, and a second-hand car in 1924 for £450, selling the former car in January, 1925, for £50.

The sale early in 1925 shows that the 1924 transaction was in the nature of a replacement rather than an addition, and, in our opinion, should be treated as if it had taken place in 1924. On that basis the expense deductible from the gross earnings for 1924 is £450 - £50 = £400.

## LETTERS, NOTES, ETC.

## TRAUMATIC INTUSSUSCEPTION.

DR. J. W. HILLIARD (Blackpool) writes: The following case may be of interest in conjunction with that reported in the *BRITISH MEDICAL JOURNAL* for April 18th (p. 734) by Dr. Mitchell. In 1901, while I was house-surgeon in the Royal City of Dublin Hospital, a boy, aged about 16, was admitted, who about eight or nine days previously had been kicked in the abdomen by another boy. Immediately afterwards he experienced abdominal pain, which continued until death, shortly after his admission to hospital. In view of the definite traumatic history the coroner ordered an autopsy, which showed that the boy had died as the result of a simple intussusception. The boy's assailant was subsequently arrested and charged with manslaughter. On being summoned to give evidence I consulted the honorary hospital staff and looked up the literature on the subject, but could find no evidence to justify the opinion that intussusception could be traumatic in origin. I explained the matter in court, and the magistrate discharged the boy.

## THE ADVANTAGES OF DRAFTS.

SINCE the note under this heading was published a fortnight ago (p. 752) we have come across expert testimony from an unexpected quarter to the importance of frequent revision if an article is to be effective. Anatole France, upon whose opinions and practice the note was based, made sure with his seven or eight drafts that what he had in mind was conveyed to his readers in the best and fewest words, in the best order; an authority (after our recent experience we will not venture to give his name) once said that was a definition of good prose. France knew that in no other way could he at once give pleasure to his reader, arrest his attention, and impress his memory. It may be said that he was thinking of the aesthetics of writing, of the essential of a good style. But our new authority is Mr. Joseph Pulitzer, the proprietor of the *New York World*, who raised that newspaper from a position of inferiority to one of commanding influence in the United States. He was a Hungarian by birth, and when he got to the United States at the age of 17 knew not a word of English. He may be supposed, therefore, not greatly to have troubled about a good English style, but in writing to a newly appointed editor he wrote: "one leader strong, a while people will, and therefore the man who writes it should touch no other thing the same day. Indeed, I will give him forty-eight hours, and make him rewrite it sixteen times." This is not a word of English. He may be supposed, therefore, not greatly to have troubled about a good English style, but in writing to a newly appointed editor he wrote: "one leader strong, a while people will, and therefore the man who writes it should touch no other thing the same day. Indeed, I will give him forty-eight hours, and make him rewrite it sixteen times." This is not a word of English. He may be supposed, therefore, not greatly to have troubled about a good English style, but in writing to a newly appointed editor he wrote: "one leader strong, a while people will, and therefore the man who writes it should touch no other thing the same day. Indeed, I will give him forty-eight hours, and make him rewrite it sixteen times." This is not a word of English.

## DERMATITIS FOLLOWING ULTRA-VIOLET LIGHT.

DR. J. GRAHAM CAMPBELL writes: I wish to express the hope that the paper by Dr. J. H. McCrea (April 11th, p. 693) will not be the last word on the subject. Further development of treatment by ultra-violet rays. To obviate untoward results it is, Dr. Campbell considers, only necessary to employ a type of lamp which cannot be used in the manner detailed. He finds that the tungsten arc lamp (Clark's pattern) fulfils all demands and gives gratifying results in affections so widely apart pathologically as tuberculous sinuses and favus, chronic ulcers and neuritis.

## HEART STRAIN.

DR. HARRINGTON SAINSBURY (London, W.) writes: Dr. Samways having reopened (*BRITISH MEDICAL JOURNAL*, April 18th, p. 761) the subject of the pressure transmitted back to the ventricle from the aorta during ventricular diastole, in the case of aortic leakage, will you allow me to point out that, inasmuch as the ventricle has more or less emptied itself during systole, it will present a potential cavity enclosed by slack walls, at the moment when, on cessation of its systole, aortic regurgitation sets in? This being so, the whole force of the aortic recoil will spend itself in the rate of flow of the backward current and none of it will be transformed into pressure within the ventricle, for the simple reason that the relaxed walls, opposing no resistance to the inflow (save the inertia of their own walls, a negligible quantity), yield passively to the influx. Only when the potential cavity has been abolished—that is, the ventricle filled—will the walls oppose by their stretch the distension of the ventricle, and only then will the aortic reflux begin to generate intra-ventricular pressure; even then, in its first beginnings, the resistance to stretch will be relatively slight, and long before it has assumed appreciable quantity the cardiac cycle will have brought back ventricular systole and saved the situation. The laws of the Bramah press are the laws of forces in balance—that is, in stasis—and rigidity of the containing walls is an essential condition. They come into consideration during ventricular systole, in that stage which precedes the forcing of the auricular valve.

## ARRESTED DEVELOPMENT.

DR. JOHN WOOD (Sheffield) writes: The following case appears to be of sufficient interest to justify its being recorded. A young lady, aged 27, private secretary in an office, consulted me in October, 1924, for very intractable constipation. As the usual remedies gave no relief, I arranged to examine her at her home, when she informed me that she had never menstruated. While exploring the bowel I discovered that she had atresia vaginae, and, on further examination, I could feel nothing corresponding to the uterus. In the left pelvis I found a distinct swelling,

which I thought might be a kidney; two surgeons subsequently confirmed this diagnosis. Arrangements were being made for an x-ray examination when the patient became very depressed, and in the following January committed suicide. I obtained permission from the coroner to open the abdomen, but was only allowed about twenty minutes for the examination. I found the uterus by connective tissue; there was no trace of the ovaries, and the ovaries were present in a rudimentary state, traced the Fallopian tubes to where they ended, just behind the symphysis. There was one kidney, weighing 6 oz., in the left side of the pelvis, with a single ureter; no suprarenal body was attached to it. There appeared to be an abnormal number of large vessels and bands of fibrous tissue passing in front of the descending colon, which, I think, accounted for the constipation and the peculiar ribbon-shaped stools. The patient had told me that she was fond of male companionship. Her mother had just died from malignant disease of the bowel, and the girl's mind became obsessed with the idea that she was similarly afflicted, which, no doubt, drove her to commit suicide.

## TREATMENT OF PUERPERAL INFECTION.

DR. F. S. TAYLOR THOMAS (Perth, Western Australia) writes to call attention to a line of treatment he has used for a number of years; since adopting it he has not lost a single case from puerperal sepsis. It is, he says, the placing in utero (after blunt curettage and gentle douching of the septic uterus to remove grosser particles of debris) of a rubber tube slightly larger than douche tubing, in which windows (six or eight) have been cut throughout the entire length of the intrauterine portion. This is kept in situ by a careful packing of the vagina with iodoform gauze. One limb is attached to an irrigator and the other limb to a piece of tubing which passes to a pail at the side of the bed. Continuous encol or weak iodine irrigation is then maintained until the temperature falls to normal (twenty-four to forty-eight hours) and the uterus begins to expel the tube by its contraction, as evidenced by the leakage under the patient, who should be placed on a Kelly's douching cushion. I am well aware, Dr. Taylor Thomas adds, that this treatment is opposed to the views of many authorities whose views one is bound to respect; but, nevertheless, all the theories of all the experts in the universe cannot get over results. I had the honour of introducing this method of treatment to the medical profession at a meeting of the Perth Branch of the British Medical Association in April, 1924, and the paper was published in the *Medical Journal of Australia* of July 5th, 1924.

## TETANUS CAUSED BY EAR LOBE PUNCTURE.

CAPTAIN S. K. CHAUDHURI, M.B.E., late I.M.S., chief medical officer Benares State, writes: In less than six weeks I have seen five cases of tetanus all due to the use of the same being pierced for earrings with dirty and the use of dirty

The incubation period ranged from four to twelve days.

Case 1.—A Mohammedan girl, aged 6, was found in an advanced condition of tetanus after an incubation period of one week. Trismus was complete, the neck muscles were stiff, and there were frequent contractions of the muscles of the limbs and back. Chloral and bromide were given internally, and 3,000 units of antitetanic serum was injected into the flank. She died on the twelfth day of the disease.

Case 2.—A Hindu girl, developed tetanus, and serum being injected.

Case 3.—A married Moh lockjaw on the fourth day. lockjaw was complete. An was given next day, followed by subcutaneous injections of 2 per cent. carbolic lotion, beginning with 5 minims once a day, and rising to 8 minims, five later on, chloroform patient frequent at making an uninterrupted recovery.

Case 4.—A Hindu girl, aged 7, showed a mild chronic condition of tetanus, the length of the inc was partial, the muscles of th of the lower limbs had lost whea attempts at walking wer lotion were given, starting with 2 minims and rising to 5 minims on alternate days, six doses in all being given. Chloral and bromide were administered internally, and complete recovery resulted.

Case 5.—A Mohammedan girl, aged 18 months, was only seen when dying, after an incubation period of six days. Carbolic lotion was injected once, but no more was heard of the patient, who presumably died.

Tetanus arising in this way is frequent, but its incubation period in the tropics is shorter than that given in the textbooks. The cost of antitetanic serum appeared prohibitive; the majority of the patients, being the children of poor people, could not be treated by the usual methods. The necessity of cleanliness, even in so simple a matter as ear piercing, is emphasized.

I am indebted to Dr. T. N. Sinha for his advice to use Baccelli's method of carbolic lotion injection, which had been very successful in his hands, though previously a failure in mine.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 195.

## An Address ON SLEEP AND SLEEPLESSNESS.

DELIVERED BEFORE THE OXFORD MEDICAL SOCIETY

BY

C. P. SYMONDS, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN FOR NERVOUS DISEASES, GUY'S HOSPITAL.

(Abridged.)

If sleep has more often provided a theme for the poet than for the physiologist the reason is not far to seek, for it contains enough mystery yet to give play to roaming fancy. For most of us there is something so inevitably right in the nightly respite from mental activity that we do not pause to consider its meaning until perhaps one night its lulling charities fail us. Then we are brought face to face with problems still, many of them, awaiting solution. What do we know of sleep in terms of physiology? How far can that knowledge help us in the treatment of insomnia?

### PHYSIOLOGY.

Actually the physiologists have not been idle; the fact that their conclusions on the whole have been of negative value is a fair measure of the difficulty and complexity of the problem. The essence of sleep is in the central nervous system, and consists of a complete cessation of conscious activity together with a greatly diminished capacity to react to environmental stimuli. With this are associated certain phenomena in the other bodily systems, and these, because they are more readily available for study, have chiefly engaged the physiologists' attention. The result has been a tendency to lose sight of the central fact, and to attempt to explain this in terms of the associated phenomena.

A theory of sleep which has obtained some credence is based upon the observation that in the sleeping state there is a fall of blood pressure and a diminution of the pulse rate. The suggestion is that at the end of the day the vaso-constrictor centre becomes fatigued. The systemic arterioles dilate, the blood pressure falls, the supply of arterial blood to the brain drops below the point necessary to maintain the activity of the cortical nerve cells, and sleep therefore supervenes. In support of this theory it has been adduced that in animals and in man pallor of the cerebral cortex may be observed at the onset of sleep, but there is so much conflicting evidence upon this point that it cannot be taken as a basis for argument.

Against the theory stand observations which show that in man the nocturnal fall of blood pressure and pulse rate occur independently of the sleeping state. Thus a man lying awake at night has a lower blood pressure than one asleep during the day.

There are, however, more serious objections to all theories of sleep based upon the idea of cerebral anaemia. It is true that cerebral anaemia, as from a severe haemorrhage, may lead to stupor, but is this directly comparable with sleep? I think not. A fundamental feature of true sleep is its restorative effect upon the higher mental faculties, an effect which is completely lacking in clinical experience of such anaemias; as, indeed, might be expected, seeing that the cerebral cortex is the most highly specialized of all tissues, and would naturally, therefore, require during the restorative sleep period a maximal rather than a minimal share of the cleansing stream.

The body temperature shows a diurnal rhythm similar to that of the blood pressure. In a person accustomed to nocturnal sleep it reaches its minimum at about 3 a.m., and this nocturnal fall persists even if the subject of investigation is awake and active. If he changes his habit and sleeps regularly by day instead of night, gradually the temperature curve is reversed, and at the end of about six weeks the reversal is complete, so that the fall is diurnal. If now the subject returns again to the habit of

nocturnal sleep, the temperature rhythm is gradually readjusted, taking about six weeks to regain the normal swing.

It appears, then, that the habit of going to sleep for a particular period of the twenty-four hours, if persisted in long enough, will initiate a corresponding periodicity or rhythm in certain bodily systems, and that this rhythm once established tends to persist on its own account independently of the sleeping state.

The diverse functions involved, and the tendency to persistence of the rhythm once established, make it extremely probable that these associated phenomena depend upon reflex centres established at a comparatively low level in the central nervous system. The effective stimulus to these centres is a combination of many conditions, of which sleep is the most important, the others being of the order of light, temperature, noise, and so on. Even in the absence of sleep, at first the other conditions are adequate to set the reflex in motion—just as, even in the absence of food, the ringing of the bell will cause a secretion of saliva in a dog accustomed by previous experience to bell and food in combination. The physiological changes which result doubtless have an effect in facilitating the regular onset of sleep for a fixed period of the twenty-four hours. The man who is transferred from day to night duty is at first still inclined to be wakeful by day and sleepy at his former bedtime.

The condition of sleep closely resembles those pathological conditions known to us as stupor or coma (according to their depth) caused by the cerebral anaemia resulting from compression of the brain, or by the action of various poisons upon the nerve cells (for example, uraemic and diabetic coma). There are, however, certain features which serve to distinguish natural sleep from pathological stupor:

1. The effect of sleep is restorative, in contrast with that of pathological stupor, from which the patient emerges in a dazed condition, with mental faculties dulled.
2. The onset of sleep is relatively rapid.
3. The awakening from sleep also is a rapid process as compared with the recovery from stupor.

4. There exists in the healthy person a remarkable ability to select by experience certain stimuli for which the threshold is relatively lowered so that they rapidly result in waking, whilst for other stimuli of equal or greater volume and intensity the threshold may be relatively raised. The most striking example in my own experience has been that of learning to sleep soundly in a shallow dug-out behind which an 18-pounder field gun was firing at frequent but irregular intervals, whilst, on the other hand, the shriek of an approaching shell at dangerous proximity would bring me in an instant to the full possession of my faculties.

Of the commoner and more homely examples one may take the ability gradually acquired by the child to respond to the stimulus of a full bladder, or that of the mother waking on the instant to her infant's cry. Such habits of conditioned awakening may be gained or lost after quite brief experience. Thus it is easy enough for some persons, and in some circumstances, to make the sound of the alarm clock a condition for a hasty leap out of bed; while for others, or in other circumstances, the same stimulus after a moment's waking may act as a profound soporific.

Less striking, but very important, as I shall hope to show in dealing with insomnia, are the conditioned stimuli which may be used to induce the sleeping state.

### THE NATURE OF SLEEP.

From these observations I believe we may draw some conclusions as to the nature of sleep. The rapid onset and rapid awakening, and especially the capacity to graft conditioned stimuli upon the acts of sleeping and waking, suggest a reflex mechanism. The notion of a reflex centre presiding over sleep has been long entertained by physiologists.

A reflex centre implies an afferent and an efferent pathway with a receptor mechanism at the one end and effector at the other. The effector mechanism in this case must be one of inhibition. Inhibition of what? Certainly inhibition of the function of conscious mental activity, and therefore of cortical activity. It appears likely that this inhibition

is achieved by a blocking of the pathways along which afferent impulses are normally streaming to excite the cortical cells. Such inhibition of afferent impulses at a stage lower than consciousness is, of course, well known. The simplest instance, perhaps, is that of the child with congenital strabismus who has learned to use either eye alternately but is incapable of binocular fusion. Given an apparatus by which the image of a bird is thrown upon one retina and that of a cage upon the other in such a way that the normal person sees the bird in the cage, the alternator sees either bird or cage—never both together; the reception of one image reflexly inhibits that of the other. In some such way we may suppose that the sleep centre, under adequate stimulation, cuts off afferent impulses from the cortical cells until they, from lack of stimuli, become inactive—inactive, that is, so far as the anabolic phase is concerned; during sleep, we have good reason to suppose, the phase of anabolism leads to restoration of their functions.

Such a conception of sleep as due to a cutting off of the cortical cells from stimuli is not only in accord with the rapidity of onset and awakening and the restorative effect of the sleeping state, but provides an explanation for the difference between sleep and stupor.

The resemblance between these two conditions is due to the cessation in both of cortical (conscious) activity. In stupor this is due to a direct effect upon the cortical cells, whose function is impaired owing to lack of oxygen or the action of poisons. There is, therefore, not only loss of consciousness but loss of potential consciousness. In sleep, on the other hand, the cortical cells are only inactive because they are protected from stimulation; consciousness is lost but potential consciousness is unimpaired. This difference has an important bearing upon the use of narcotics.

So far we have been considering only the efferent side of the postulated reflex arc. On the afferent side the adequate stimulus is probably a fatigued state of the cortical cells themselves, which is usually associated with a sense of weariness and the desire for sleep. This leads normally to a series of voluntary actions directed to the elimination of external or internal stimuli. Of these actions the most important is the assumption of the resting posture in which the muscles are relaxed and proprioceptive stimuli from them and from the joints are reduced to a minimum. Other measures, such as withdrawal from light and noise, are of secondary importance, but may acquire an additional value as conditioned stimuli. In fact, a great variety of conditioned stimuli may be developed which in proper sequence and combination facilitate the sleeping reflex. On the other hand, the association with the pre-sleep period of unwanted stimuli may serve to prevent the development of the reflex.

As to the localization of this hypothetical sleep centre, it has been suggested that it lies either in the walls or floor of the third ventricle or lower down in relation to the Sylvian aqueduct. The evidence adduced is the frequent association of pathological drowsiness with lesions in this neighbourhood.

#### A CLASSIFICATION OF INSOMNIA.

As a provisional classification of the insomnias I would suggest the following:

A. *Insomnia due to Disease directly involving the Sleep Centre:* The classical example is in certain cases of encephalitis lethargica.

B. *Insomnia due to Overexcitability of the Cortical Nerve Cells as the Result of Intoxication or Anaemia.*—This is seen in the course of many infections, in the preliminary stages of uraemia, lead poisoning, etc., and in minor degrees of cerebral compression, as from cerebral oedema after a head injury.

C. *Insomnia resulting from the Presence of Unwanted Stimuli which Inhibit the Sleep Reflex.*—This is the largest and most important group. There is a variety of stimuli which are able to withstand the reflex inhibition upon which sleep depends, to break through this barrier to the cortical cells, and to excite these to activity. Their power to achieve this the sleep reflex has been rendered prepotent, either by cortical fatigue or the strengthening effect of conditioned stimuli. The most familiar causes of this group are:

1. *Muscular Posture and Tension.*—It is impossible to sleep and remain sleeping in the standing posture. Even at the end of 115 hours' continuous insomnia, when the desire for sleep was imperative, Kleitman and his co-workers found that the onset of sleep could be prevented by moving about.

2. *Pain* (including discomfort, as, for instance, from irritation of the skin or extremes of temperature).

3. *Emotional Excitement.*—At this point it becomes extremely difficult to pursue my argument in physiological terms. We must recognize, however, that an emotion, whatever its physiological origin, is a potent stimulus to conscious activity, and chief among the emotions in this respect is fear.

#### THE TREATMENT OF INSOMNIA.

##### Drugs.

The essential feature of the sleeping state is inactivity of the cortical cells concerned with conscious activity. This is also the essential feature of toxic stupor. According to our theory, however, the distinction between the two states is that in sleep the cortical cells are inactive because they are shut off from afferent stimuli: in stupor their activity is abolished by the direct action upon them by a toxin. This bears an important relation to the use of narcotic drugs, whose action is also directly upon the cortical cells, and is, of course, toxic. It is possible with the aid of narcotics to induce stupor by paralysis of the cortex without endangering life, because the vital reflex centres are relatively immune to their action. It is possible thus to induce the semblance of sleep even against heavy odds in the shape of discomfort and anxiety.

But this is not the real thing: the restorative effect is lacking; and the patient therefore does not wake properly refreshed. You will remember in this connexion Othello's sleepless night after the seeds of suspicion had been planted in his mind, and Iago's greeting:

"Not poppy, nor mandragora,  
Nor all the drowsy syrups of the world,  
Shall ever medicine thee to that sweet sleep  
Which thou ow'dst yesterday."—*Othello*, Act iii, Sc. 3.

No one, however, would deny that narcotics are of the greatest value in the treatment of insomnia. And this for two reasons: First, the toxic effect of insomnia upon the cortical nerve cells may be more severe than that produced by the drug. It is a well known fact that insomnia may lead to depression of the higher mental faculties, and eventually to coma and death. In the second place, small doses of narcotics often facilitate the onset of true sleep. I do not propose to go into detail of drugs and their doses. Bromide alone, or in combination with chloral; paraldehyde for a quick action; sulphonal for delayed effect; medinal as a useful all-round narcotic; the coal-tar analgesics and opium for pain or discomfort, comprise the therapeutic stock-in-trade.

##### Habit Formation.

Of the value of conditioned stimuli in facilitating sleep I have already spoken. Most of us have acquired a ritual of some kind—perhaps unconsciously—which stands us in good stead when sleep is threatened; it includes the whole business of undressing and getting into bed; the habit of reading in bed is often a part of it. For this reason I think that an invalid, whenever it is practicable, should sit up in a chair just before bedtime while his bed is made, so that he may not altogether miss the experience of going to bed.

Unfortunately, when sleeplessness has persisted for any length of time the old rituals lose their value, and may even facilitate insomnia. Then is the time to initiate new rites, beginning by moving the patient, if not into another house, at any rate into a fresh bedroom. The ritual may consist of some such sequence as the following: a warm bath, into bed, a cup of warm milk or an equivalent, then a solemn plugging of the ears with cotton-wool, perhaps five minutes' reading by the bedside lamp, and then lights out. The sleeping draught, if any is prescribed, may be taken before or with the warm drink. As a finishing touch, I recommend the repetition by heart of some soporific verse. Keats's *Ode to Sleep*, in my experience, is insurpassable in this respect. Such a ritual must be persevered in if it is to be efficacious.

*Muscular Relaxation.*

Sleep, as we have already observed, is incompatible with any great degree of muscular tension, and there are some individuals who are kept awake largely by their inability to relax their muscles. The tendency for the sleepless person being to toss and turn, it is important that he should learn that this in itself is fatal to sleep, and that the wisest plan is to lie perfectly still. Even though this may demand a certain amount of effort and self-control, it will often induce sleep.

The efficacy of this principle in treatment has been shown to no most clearly in certain cases of encephalitis lethargica in children, where motor restlessness has been the most prominent symptom of the insomnia. After the preliminary rites of warm bath, sleeping draught, and ear plugging, the child is tightly rolled in a long sheet which is fastened with safety-pins, the arms being included so that he is immobilized. The results in some cases have been striking—for instance, a sleep of nine hours with the pack, as compared with a maximum of four and a half hours when the other measures alone were employed.

Beyond this, there is an art in muscular relaxation, as anyone may prove by attempting to allow one of his limbs to be absolutely passive in the hands of another person. It is an art which patients can be taught to acquire limb by limb until they can themselves practise complete bodily relaxation. The soporific effect of this exercise is sometimes of great value; it may be taught by an instructed masseuse, and may be usefully included among the final stages of the bedtime ritual.

*Details of Treatment.*

The insomnia due to disease of the sleep centre, such as I believe occurs in encephalitis lethargica, is, in my experience, the most difficult of all to treat. In many cases, as the normal sleep time comes round, the cortex appears to pass into a condition of great overexcitement, and this occurs night after night for many weeks with the greatest regularity. It is tempting to believe that in these cases reflex inhibition has been converted by the disease into reflex excitation, and that the cortical cells are thus being abnormally bombarded with afferent stimuli. A combination of drugs and ritual, if persisted in for a long time, sometimes appears to be effective, and immobilization, as already described, is valuable in patients with great motor restlessness. But these cases are, on the whole, disappointing.

The toxic and infective group of insomnias should be treated on the same lines. Here the direct effect of the toxins upon the cortex is, as a rule, reinforced by sources of pain and discomfort. Opium therefore is the most useful drug, and, in cases which are likely to be of short duration, may be used freely. In the chronic cases small doses of medinal combined with aspirin are useful. It is in dealing with this group of cases, however, that it is most important to remember the poisonous nature of the narcotic drugs. The ritual therefore should be made use of as far as possible, and the dose of drugs kept low.

The third group of insomnias—that in which sleep is prevented by unwonted stimuli—offers most scope for treatment. Pain and discomfort must be treated by local measures, and, if necessary, with drugs—*aspirin* or *opium*. The treatment of muscular tension as a factor in insomnia has already been discussed.

We have finally to deal with emotional disturbances. The emotions which have most power to disturb sleep are naturally those which are painful. Paramount are fear and anxiety. We may further distinguish between the open and hidden emotion.

A. An emotion which is present to the waking mind—a declared worry with all its associated memories binds the onset of sleep.

B. An emotion which has in the waking state been prevented from exciting conscious activity (that is, in the psychological sense, a repressed emotion) may cause insomnia in either or both of the following ways:

(1) Either the subject finds himself thinking furiously upon some indifferent subject in order to prevent the repressed worry from reaching consciousness, and so is unable to go to sleep; or

(2) He may go to sleep, but is awakened by the repressed emotion forcing its way into consciousness, often in the shape of a dream or nightmare.

The distinction between these two forms of worry—the superficial and the deep—seems to have been present in the mind of Keats when he wrote in his *Ode to Sleep*:

"Then save me, or the passed day will shine

Upon my pillow, breeding many woes;

Save me from curious conscience, that still lords

Its strength, for darkness burrowing like a mole."

In the latter type of case, in which insomnia is due to repressed anxiety, much can be done by means of judicious analysis and psychotherapy. Free ventilation and frank discussion of the underlying emotional conflicts is the essence of successful treatment.

The open worry, as a rule, is short-lived and resolves itself. Being of an occasional nature it may be justifiably treated with drugs. A whisky and soda at bedtime is often sufficient. It is most important, however, that sleeplessness of emotional origin should be taken in hand early, for the habit of insomnia is readily acquired, and we are then apt to encounter as a perpetuating cause of sleeplessness the anxiety about sleep. The patient goes to bed with the fear that he will not sleep, and this fear, gathering around it thoughts of the morrow's duties, successfully inhibits the sleep reflex and excites cortical activity. This fear must be treated from the start with absolute reassurance. As a cause of unpleasant symptoms the importance of insomnia must be minimized in the patient's sight. Finally, in a case in which this particular anxiety appears to be mainly responsible for the trouble, the patient may be given an effective draught—a drachm and a half of paraldehyde or  $7\frac{1}{2}$  grains of medinal, with the assurance that he will have a good night's sleep. If this follows, the same draught or cachet should be placed by his bedside on subsequent nights, with instructions that he should take it, *without hesitation*, if he is unable to sleep. If the case has been judged correctly this line of treatment succeeds. The presence of the drug by the bedside in itself allays the anxiety, and the patient sleeps soundly without taking it. After a few nights of this kind he ceases to bother about the drug, and as far as his insomnia is concerned may be considered cured.

In the treatment of the emotional insomnias bedtime ritual and muscular relaxation are both of value; the former may also be made a vehicle for reassurance; the latter is most useful in those individuals whose anxiety reflects itself in muscular tension. But the narcotic drugs are also essential in the majority of cases. That they should be at the same time more beneficial and more permissible in this than in other types of insomnia is intelligible in the light of our theory. Here we have the sleep reflex prevented by stimuli arising within the nervous system at a high level of cerebral integration. The cells in which these stimuli arise are therefore themselves susceptible to narcotic drugs in much the same degree as those cells which we have supposed to be concerned with consciousness.

Drugs may therefore be given regularly, at first in sufficient doses to ensure sleep, while at the same time the other therapeutic measures of psychotherapy, habit formation, and relaxation are employed with the object of re-establishing the natural rhythm. After the patient has had a succession of four or five good nights the dose is gradually reduced; the other measures, of course, being continued. In employing this method of treatment we are liable to encounter one of two difficulties—the patient is liable, on the one hand, to develop anxiety lest he become a drug habitué, or, on the other hand, when he finds that his dose is diminished, he may be kept awake by the renewed fear that to-night he will not sleep. This difficulty may be met by explaining to the patient from the first the rationale of the treatment and telling him that the dose will be reduced without his knowledge. This is easily done if the medinal is given in cachets. The size of the cachet and the amount of its contents are kept constant by replacing the medinal subtracted by sodium bicarbonate. The patient may thus be allowed to go on taking the cachets until he can be told he has now been sleeping soundly on nothing but sodium bicarbonate for several days. Or the cachet may be incorporated as a part of the bedtime ritual for some time longer before the disillusionment is completed.

## Lancian Lectures

ON

SOME FORMS OF VOMITING IN  
INFANCY.DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS  
OF LONDON, MARCH-APRIL, 1925,

BY

H. C. CAMERON, M.D. CAMB., F.R.C.P. LOND.,  
PHYSICIAN IN CHARGE OF THE DEPARTMENT OF DISEASES OF CHILDREN,  
GUY'S HOSPITAL.LECTURE III.—SOME FORMS OF "HABITUAL  
VOMITING" IN INFANCY.

IN my first lecture I dealt with vomiting due to high obstruction from developmental defect; in my second with vomiting due to the imperfect working of the sphincters of the stomach and intestines. There remain a number of other conditions, marked by persistent and severe vomiting of more obscure etiology, but more frequent occurrence, which are best grouped together under the name "habitual vomiting of infancy."

## VOMITING AND AEROPHAGY.

In the first place it will be well to consider the part played by aerophagy in the causation of habitual vomiting in early infancy. Every infant normally swallows considerable quantities of air mixed with the milk. Upon the breast this admixture is generally greater than when the infant is carefully fed from the bottle. The difficulties of breast-feeding are seldom due, as they commonly are in the unnatural feeding with artificial substitutes, to abnormalities in the chemical reactions within the stomach. The infant is the suction apparatus, upon the efficiency of which both the quantity and quality of the milk in great measure depends, and the difficulties of successful breast-feeding are largely concerned with the problem of securing effective adaptation of the suction apparatus to the nipple. With the bottle, on the other hand, the flow of milk is so easy that it calls for comparatively little effort on the part of the child. If a young infant is taken from the breast and given a bottle instead, it is a common experience to find that excessive aerophagy is at once diminished, together with its attendant troubles of pain, hunger, restlessness, and vomiting. A mother who has had this experience is likely to conclude that the quality of her milk had been at fault and to confuse what resulted from a want of adroitness in the infant's suction with a true dyspepsia. Her mistake will be tragical if, as often happens, a true fermentative dyspepsia is established by the unnatural diet and the infant exchanges for its former discomfort a dangerous and perhaps even fatal disorder.

Examination by means of the x rays of infants after breast-feeding shows clearly the extent of the normal aerophagy. At this early age in order to study the distension of the stomach with gas an opaque meal is unnecessary. While the meal is being taken the stomach of the nursing allows itself to be passively distended with the swallowed milk and with the swallowed air. By the end of the meal it is usual to find that the intake of air within the stomach has reached very considerable dimensions. For some time after the ingestion of the milk there may be no movement on the part of the stomach to contract down upon its contents—that is to say, the so-called peristolic function of the stomach is delayed. At length, after an interval—it may be perhaps after five or ten minutes—it is usual to note a somewhat brisk contraction of the stomach which expels a considerable part of the swallowed air with an eructation which is clearly audible. The practice common among nurses of holding the infant upright to assist in the expulsion of the wind is justified by what is apparent under the x rays. In that position the air ball lies most directly under the oesophageal opening, so that eructation without escape of fluid or with only a minimal escape of fluid is facilitated. If, on the other hand, the child is laid down upon its back the air ball may be prevented

from escape by the intervention of fluid. Eructation then requires a very violent contraction of the stomach, and is apt to be accompanied by regurgitation of much of the stomach contents.

Aerophagy, a normal process and one which is always found in some degree to accompany the swallowing of milk, may be so excessive as to become pathological. Thus severe nasal obstruction, as might be expected, in a young infant interferes greatly with effective suction. The hold upon the nipple must be constantly broken, in order that a hurried breath may be caught. A nasal catarrh in a young infant is a serious misfortune, not only because it involves a considerable risk of direct extension to the bronchial tubes and to the middle ear, not only because it commonly gives rise to profound gastro-intestinal disturbance, but because the diminished power of suction which accompanies it endangers the whole process of lactation. The suction of the infant, hurried and intermittent because of the dyspnoea, fails completely to empty the breast; the yield declines; the flow becomes increasingly scanty, and the inordinate efforts of the infant result only in the distension of the stomach with swallowed air (Fig. 1).

But a still more frequent cause of excessive aerophagy is to be found in what may be called the vicious circle of nervous unrest. The reflex act of suction in the young infant only proceeds powerfully and effectively when the child is quiet and at rest. When, on the other hand, the child is too eager and too excited, as it is apt to be after much hungry crying and persistent sleeplessness, a voluntary effort at suction seems to be attempted and takes the place of the more instinctive reflex act. Like all other voluntary movements at this early age, such suction, though violent and eager, is inordinate and ill controlled. The infant greedily grasps at the nipple, sucking, swallowing, choking, and even crying, all at the same moment. Such a procedure rapidly leads to a distension of the stomach with air. Suddenly the violent efforts at suction cease, and the restlessness and crying break out afresh. Ineffective suction of this sort causes a rapid deterioration in the quantity and quality of the milk. Hunger grows apace. The persistent sleeplessness and restlessness of the child, because of the immensely increased expenditure of energy, raise the needs for food far above the normal at a time when the natural powers of suction are inhibited by the emotional disturbance, and when the mother's milk is diminishing in amount.

Such is the vicious circle which accounts for by far the greater part of the failures in the early weeks of lactation to establish and continue breast-feeding. It involves, it is true, a failure on the part of the distracted mother, but a failure, I think, not primarily of her mammary secretion, but of her power to quieten and control the restless nervous system of her infant. It has always seemed to me that the emotional instability of the human infant, to which in the animal kingdom we find nothing at all comparable, accounts for the comparative frequency of its failure to win sustenance from its mother's breast.

The most striking instances of distension of the stomach with air which I have encountered have all been in infants suffering in this way from sleeplessness, hunger, nervous unrest, and inordinate suction (Fig. 2). In states of primary inanition, where the initial fault is a failure of the mammary secretion and not a failure of nervous control in the infant, I do not think aerophagy is common.

If suction is powerful and effective, as it is in a strong and placid infant, aerophagy is at a minimum while the yield of milk is at a maximum. In these circumstances, when, some time after the conclusion of the meal, the stomach contracts in the so-called peristole, there is apt to be a gentle regurgitation into the mouth of a little milk, mixed with the swallowed saliva and gastric juice. This is the so-called possetting. In every country, as might be expected, we find a proverb to the effect that possetting is the mark of the thriving, well nourished, and contented child. On the other hand, with a greater admixture of the stomach contents with air, the repeated eructation of air may be necessary before comfort is assured. In some cases the eructation is accompanied by the forcible regurgitation

of a considerable part of the stomach contents. The peristaltic contraction of the stomach is exaggerated and violent and the resultant vomiting forcible and explosive. The sound of the escaping air is usually audible. Habitual vomiting due to aerophagy is apt to be mistaken for that due to pyloric spasm or even far that due to hypertrophic pyloric stenosis. Visible peristalsis, pyloric tumour, and the characteristic inanition stools are, however, here wanting.

Different authorities have estimated very differently the importance and frequency of aerophagy as a cause of habitual vomiting. Marfan, who has recently dealt very fully with the whole question, regards the aerophagy, not as a primary, essential, and constant factor, but as something secondary, contingent, and variable. According to his view the essential cause is to be found in a hyperaesthesia of the gastric mucous membrane, a hyperaesthesia which may favour the purposive swallowing of air and the secretion of excess of saliva, while the distension of the stomach with the swallowed air may favour the vomiting. On the other hand, Lesage, Guinon, and others in France, Rosenstern and Usener in Germany, have argued convincingly for the importance of air-swallowing as in itself a cause of habitual vomiting. Certainly the results of treatment directed to control and prevent aerophagy, but in no way calculated to allay gastric hyperaesthesia, are sufficiently constant to suggest that the air-swallowing is of primary importance in causing this variety of habitual vomiting.

#### *The Treatment of Habitual Vomiting due to Aerophagy.*

1. Thus it is by no means unusual to find that the infant, invariably sick after a breast-feed, will retain the feed without difficulty if it is given carefully from a bottle, even when the contents of the bottle are composed of the same breast milk which is vomited when sucked directly from the breast.

2. If the infant in whom the aerophagy is due to inco-ordinate suction as a result of nervous unrest is fed, not when hungry and excited from long crying, but when drowsy and quiet, there may then be no aerophagy and no subsequent vomiting. In the out-patient department at Guy's Hospital I have very often demonstrated this point. In an infant 1 or 2 grains of chloral hydrate given a few minutes before the meal is usually sufficient to secure a quiet and drowsy state. If then the mother's nipple is gently inserted into the mouth of the slumbering child, without awakening it and without provoking the restless emotional state, the breast may be drained steadily and well, there may be no subsequent vomiting, and the infant may continue to sleep soundly after the meal.

3. Recently Rogatz and others have studied under the x rays the effect of giving a small amount of a thickened food before the usual feed of breast milk. The characteristic x-ray appearance of the stomach of the infant is determined, not by anatomical peculiarity, but only by the circumstance that the diet is always and invariably fluid. Under ordinary conditions the stomach of the infant shows no tendency to contract down upon the entering milk, while the fundus remains distended with a huge ball of air. The contraction of the stomach, the peristaltic contraction, can be stimulated by giving comparatively small amounts of a semi-solid substance—one or two tablespoonfuls, for example, of a very thick gruel. A paste of farina, in the proportion of 10 grams of farina with 100 c.cm. of skim-milk and 100 c.cm.

of water, boiled for an hour until sufficiently thick to adhere to an inverted spoon, may be given in doses of 30 c.cm. before the breast-feed. A semi-solid mixture of this sort is capable of producing a brisk contraction of the stomach, so that its distension by air during the subsequent suction at the breast is prevented. On several occasions I have found this device completely successful in allaying habitual vomiting of long duration and great severity. In one case the infant was sent to me at the age of 9 weeks with the suggestion that it was suffering from congenital hypertrophic stenosis. The mother reported to me some weeks later that on one occasion had the baby ever been sick when the gruel had first been given, although vomiting still almost always followed breast-nursing if this preliminary was omitted.

The success of treatment upon one or other of these lines is in keeping with the assumption that aerophagy by itself may be the essential cause of some cases of habitual and violent vomiting.

#### VOMITING AND NERVOUSNESS.

It requires small experience of infantile disorders to convince oneself that the infant who suffers from hyperemesis is almost always tense, nervous, emotional, and more than usually unstable. Such infants, indeed, seem to suffer from a generalized hyperaesthesia. A loud sound, a bright light, or a sudden movement in their neighbourhood produces a maximum response. From the first, too, the heightened sensibility of the nervous system is apt to show itself in an extreme sensitiveness in the matter of taste. The slightest alteration in flavour—the prescription, for example, of dextrimaltose instead of the lactose to which it has become accustomed—may cause resistance or refusal or vomiting. Sleep is almost always scanty and superficial.

In response to the slightest stimulus, instantly the child is wide awake, the anxious strained expression flows back into the face, and the inevitable crying begins again. In these neuropathic infants the muscles generally show a certain degree of hypertonus. The abdominal wall tends to be rigidly contracted, with the outline of the recti abdominales clearly visible. Opisthotonos is common, while the hands are nearly always held tightly clenched. Such infants may appear to suffer from a veritable gastric hyperaesthesia. The presence of food in the stomach may evoke every appearance of extreme pain and discomfort and may be followed regularly by vomiting, whether the infant was fed upon the breast or the bottle. Habitual vomiting of this sort may occur in such children even when there can be no question but that the food is suitable in amount and in composition. Sometimes in later years other troubles arise which give the clue to the constitutional weakness which first

manifested itself in this infantile gastric disorder. In inquiring into the past history of children with such functional nervous disturbances as enuresis, asthma, stammering, habit spasm, and so forth, a considerable proportion will be found to have suffered in this way in early infancy. Again, the appearance of eczema in later infancy has been noted by Finkelstein and others.

#### *The Treatment of Vomiting due to Nervous Unrest.*

The treatment of this nervous vomiting may be a matter of great difficulty. One thing makes itself very clear—that it is always an unwise and unsuccessful manoeuvre to attempt to allay the vomiting by prescribing a hunger

FIG. 1.—Showing extreme distension of the stomach with swallowed air after a breast feed, in an infant with nasal obstruction and mouth breathing.

FIG. 2.—Showing extreme distension of the stomach with swallowed air, in a breast-fed infant with inco-ordinate excited suction and nervous unrest.

period or by diluting the food or curtailing the total amount given. Such devices, essential in treating the ordinary form of infantile dyspepsia, only serve to make this habitual vomiting of the nervously unstable child very much worse. Indeed, it is remarkable that in many cases the weight curve will continue to ascend and the nutrition will remain unimpaired in spite of violent and persistent vomiting. In practice it is common to find that serious malnutrition is caused not so much by the vomiting as by unwise efforts to control it by the prescription of an inadequate diet or a diet modified to such an extent as to be deficient in certain essentials. It is, however, usual to find that the stomach is especially intolerant of a diet with a high proportion of fat. It is apparently the volatile fatty acids which especially possess for these infants an emetic action. One such infant under my care was almost invariably sick after the breast, and after the fifth month of life, when weaning took place, after a meal of cow's milk, even in considerable dilution. Upon a diet of milk from which fat was removed until the percentage was never higher than 1.5, and which was then soured with a lactic acid bacillus, vomiting was only occasional, and a satisfactory growth of weight was achieved. In all, three attempts were made to return to a diet with a higher fat percentage, but always with renewal of the vomiting. With these restless, hypersensitive infants it is above all necessary to avoid the stimulus of excessive hunger, and to see to it that the needs for food are amply covered. In this we are reminded of what is found to be the rule by Hurst, Fairbairn, and others in the treatment of hyperemesis gravidarum and certain other forms of nervous vomiting in adults. Treatment, if it is to be successful, must aim, not so much at controlling the vomiting as at allaying the nervous unrest. Such vomiting often ceases as if by magic when the infant is admitted to a hospital or when the confident handling of an experienced nurse succeeds to the too timid and anxious control of an inexperienced mother. Rest, quiet, and the absence of all stimulation are essential. Prolonged immersion in a hot bath, or a hot pack, may secure sleep and start the habit. Enveloping in a tight and restraining shawl—the primitive wisdom of all peoples has taught them the value of swaddling clothes, the infantile strait-waistcoat, in securing rest—is often helpful. The habitual vomiting of nervous unrest ceases only when deep sleep is secured and the restlessness sensibly diminishes.

Other forms of persistent vomiting due to nervous causes are occasionally encountered. Thus, in older infants, we sometimes meet with vomiting which might be described as due to a conditioned reflex. Thus one particular meal, although its composition differs in no way from that of the others, given at one particular time of the day, alone may be consistently rejected. Or it may be that a meal given by a particular person, or in a particular room, alone is vomited. Again, by the end of the first year it is quite common to meet with a purposive rejection of food as part of the anorexia nervosa of nervous children. With unwise management the dominating, restless child is apt to show to perfection the symptom which has been called "negativism." Whenever the maternal traction in one direction is exercised too obviously and insistently the child seems forced into a posture of resistance. As might be expected, the struggle waged between the child and its elders is apt to involve the question of the intake of food. The more the child is urged and entreated to take the food, the more resolute is the opposition. Many mothers have told me that in such circumstances the only way in which they have succeeded is by feeding the baby when it is asleep. They have crept to the side of the cot and aroused the child just sufficiently to admit the teat of the bottle into its mouth and to provoke the act of suction. But if they have accidentally wakened the child too thoroughly so that complete consciousness of its surroundings has returned, the first waking thought has been of the habitual refusal, and the bottle has been pushed away with every sign of determined rejection and resistance. It is characteristic of this negativistic attitude to food that when the unwise urgings of the anxious mother cease food may be taken with avidity. Thus older children,

having refused all food at the table, will descend upon the floor and greedily scavenge for crumbs. Two mothers told me recently that the best meal their children made in the day was when, with a parcel of unappetizing crusts for the ducks in the park, they took their walks abroad. Most of the crusts were then consumed by the children, and one of the mothers had even got into the way of including certain nutritious pieces of brown bread-and-butter in the parcel in the sure hope of its consumption by the child. If, in dealing with such a trying case, force is attempted and a strong-minded woman with uplifted spoon attempts to feed the child against its will, vomiting almost certainly results, and I have met with more than one case in which vomiting, clearly originating in this way, has persisted as an inveterate neurosis for many years. In some cases the sight or sound of the preparation of food has sufficed always to produce vomiting. It is clear that the more attention that is paid to vomiting of this sort, the more it is discussed and deplored in the child's presence, the more inveterate does it become. Such disturbances are not, however, difficult to control if their nature is clearly understood and the faults of management to which they owe their origin are corrected.

#### HABITUAL VOMITING AND IDIOSYNCRASY AGAINST COW'S MILK.

Something must be said of the views, expressed in an extensive modern literature, that the explanation of a large part of the difficulties which are encountered in attempting to feed the infant upon a diet of cow's milk is to be found in a frequent intolerance for the protein of the foreign milk whereby certain anaphylactic reactions are determined. Certainly from time to time we do meet with infants who exhibit the most extreme intolerance for even minimal amounts of cow's milk. Kleinschmidt, Finkelstein, Park, and many others have studied and recorded cases of this nature. The characteristic symptoms are sudden extreme pallor, drowsiness, a rapid almost imperceptible pulse, pyrexia, vomiting, and diarrhoea, often with the passage of blood-stained stools. Less usually scarlatiniform or morbilliform rashes are added to the picture, or transient oedema. Glycosuria may occur. This violent and characteristic shock may be provoked by minimal amounts of cow's milk. Thus in Park's case a considerable reaction was produced by the ingestion of four drops of milk. An appreciable reaction has even been produced by a single drop. The symptoms may begin immediately after the intake of the milk, or rather unaccountably they may be delayed for several hours. They may occur the first time cow's milk is given to the infant instead of the breast, on which it has so far thrived, or the trouble may develop at any time subsequently throughout infancy. Recovery is rapid when milk is withdrawn. Goat's milk may be perfectly well tolerated when cow's milk produces dangerous symptoms. Schloss, who has devoted great attention to these cases, finds that many infants, who show profound disturbance when given raw cow's milk, can tolerate boiled or dried cow's milk without difficulty. In the majority of these cases, although not in all, a positive cutaneous test has been found. Schloss is of opinion that the lactalbumin rather than the casein is the protein usually responsible. Many infants recover spontaneously, but success is claimed both for desensitization by the subcutaneous injection of graduated amounts of sterilized milk, and for desensitization by ingestion of graduated amounts by the mouth. Such severe cases of intolerance for cow's milk, although they undoubtedly occur, are admittedly of extreme rarity. They fall into line with cases which show a similar intolerance for the protein of eggs and for certain vegetable proteins.

Recently, however, Weill and others in France have gone much further and have found the explanation of many cases of habitual vomiting in infancy, as well as of many cases of urticaria, eczema, atrophy, and malnutrition, in a similar but mild form of anaphylaxis against cow's milk, and even against the milk of the mother. According to Weill, subcutaneous injections of milk may give rise to the most remarkable and unmistakable improvement. The first symptoms to improve are those of the nervous system.

Within twenty-four or forty-eight hours the agitation and insomnia are greatly lessened. The vomiting is more slow to disappear, but improvement is likely to appear within a week or ten days. For a cure some three or four injections are usually necessary.

Professor Marfan has not been able to substantiate such precise claims. My own experience of treatment in this way is altogether too slight to enable me to speak either in its favour or otherwise. I feel that the whole subject is in need of careful investigation, in view of the work and claims coming from many quarters.

#### HABITUAL VOMITING AND RUMINATION.

The phenomenon of rumination in the adult and in the older child has been dealt with with great fullness in an interesting paper by Brockbank in 1907. In most of the recorded cases the peculiarity is familial, acquired involuntarily in later childhood, and persistent throughout life or at least for a great part of life. The act of regurgitation is partially under the control of the will. With an effort it can be prevented, and the ruminator whose aesthetic sense is offended by his infirmity may for long escape detection. Brockbank does not discuss the relationship between his cases of rumination in adults and the much more common rumination of infancy. Probably they are not closely connected. In no case of rumination in infancy have I found a family history of rumination, and the after-histories of infants who show this symptom do not disclose, unless it be in exceptional and so far as I know in unrecorded cases, persistence of the habit into later life. In general it is characteristic of infantile rumination that it ceases when solid food replaces the fluid diet. Adult rumination, on the other hand, appears to begin after the milk period, and to occur only with solid food. But the most striking difference would appear to lie in the attitude of mind of the sufferer. The adult ruminator suffers no discomfort; Brockbank even records cases in which the act was pleasurable. But, in general, in adults the regurgitation is not the culmination of a series of movements, voluntarily undertaken and steadily pursued until success is achieved. The adult does not seem impelled to evoke the act in order to achieve a sense of present satisfaction, nor does he evince signs of nervous irritation if thwarted in his purpose. In the infant, on the other hand, it is very evident that achievement of his purpose produces a sense of beatitude, while failure results in nervous unrest and irritation.

#### Pathogenesis.

In early infancy, when sensation is awakening, certain stereotyped movements, calculated to evoke certain sensations, are apt to become fixed by repetition until they grow habitual. Since the mouth and tongue are most richly endowed with sensory nerve endings, as might be expected, the most common action of this sort is thumb-sucking or lip- or tongue-sucking. Head-banging, thigh-rubbing—that is, infantile masturbation—and rumination have precisely the same significance. No doubt in these latter instances there may have been originally some transitory local irritation which led to the first movements being practised—in thigh-rubbing vulvar irritation, in head-banging irritation from slight otitis media, in rumination some trivial gastric discomfort. But long after the local irritation has subsided the act may persist with ever-increasing frequency. In sucking thumb or lips it is not necessary to suppose the existence of any preliminary irritation which has attracted the child's attention to the part. The act of suction alone is instinctive, and needs nothing to provoke it except the presence of something to suck.

These lowly forms of gratification from sensory stimulation are normally found only in infancy. As the mind awakens and the level of intellectual enjoyment arises, as the child's thoughts become filled with recollections of yesterday's happenings and anticipation of to-morrow's, these habits and these joys are forgotten. They are perpetuated only when unwise forbiddings and expostulations or the injudicious use of mechanical restraint, the object of which is appreciated by the child, have served to awaken ungratified longing, to focus attention on the fault, and to

impress it deeply upon the memory. Finally, if the grown-up people around the child show distress or anxiety, the child very readily catches the general restlessness and apprehension. No one of these stereotyped acts shows better these general characteristics than does rumination.

Ylppö and others have maintained that aerophagy plays an important part in the production of rumination, but the consensus of opinion is against this view. Gastric disorders of all varieties may serve as predisposing causes, but no connexion between rumination and any particular gastric disorder can be clearly established. Gött appears to me right in arguing that all the features of rumination show its relationship to the stereotypias, not to the dyspepsias. *Post-mortem* observations have disclosed only a stomach in extreme systole.

#### Symptomatology.

The onset is perhaps never before the fourth month of life. It is seldom well developed or typical before the sixth month. I have had the opportunity of studying carefully five well marked cases, besides a number of slighter and less developed examples, in infants who, for all their efforts, never perfected themselves in the practice. All my cases have been in artificially fed infants. After taking the meal quite in the ordinary way the baby, as a rule, lies quiet for a time. Then begin certain purposive movements, by which the abdominal muscles are thrown into a series of violent contractions—the head is held back, the mouth is opened, while the tongue projects a little and is curved from side to side so as to form a spoon-shaped concavity on its dorsal surface. After a varying time of persistent effort, sometimes punctuated by grunting or whimpering sounds, expressive of irritation at the failure to achieve the expected result, with each contraction of the abdominal muscles milk appears momentarily in the pharynx at the back of the mouth, as the column of fluid is pressed upwards through the stretched oesophagus. In this way the head of the column of milk may be momentarily visible many times as it attains its highest point, only to fall back again out of sight when the pressure is relaxed. Finally a successful contraction ejects a great quantity of milk forwards into the mouth. The infant lies with an expression of supreme satisfaction upon its face, sensing the regurgitated milk and subjecting it to innumerable sucking and chewing movements. Some of the milk may escape from the mouth and in that sense be vomited. In a well marked instance much the greater part is caught and retained.

The power to ruminate successfully is not suddenly acquired. In the earliest stages, before dexterity has been achieved, the act differs relatively little from that of vomiting. Similarly the number of masticatory movements as a rule progressively increases. At first there may be ten or twelve, later several hundred such movements may follow the regurgitation. In its earlier development, therefore, rumination is very apt to be mistaken for habitual vomiting due to other causes, and it may require careful observation to make the distinction evident. Nor are such babies easy to observe. It is characteristic of the ruminating child that it sins its sin only in secret. To watch it openly is to put a stop to the whole procedure. Hence the great difficulty of securing a satisfactory radiographic examination. On every occasion on which I have tried to secure a radiograph the infant has shown no disposition whatever to indulge. I had hopes of being able to enliven this lecture by a cinematograph display of a well marked case, but my failure was again complete for the same reason. Only when the child is alone and in a drowsy, vacant state, while nothing distracts attention or excites curiosity, does the act take place. Ruminating infants are almost always alert, excitable little creatures, their faces lit with an unusual variety of expressions. As a rule, rumination can only be observed by stealth, by peering through peep holes, between screens, and so forth.

The nutrition commonly suffers to some extent, and the infants tend to be considerably under weight. This is especially marked in the early stages, when regurgitation is accompanied by the escape of a great part of the food. Under the impression that the disorder is a true vomiting

indicative of some form of dyspepsia, many of the cases have undergone severe restriction in their diet, or the food may have been modified, with unfortunate results. The condition may persist for many months. In the most severe, death from hunger or from intercurrent infection may occur.

#### Treatment.

For a time to distract the infant's attention seldom fails, but always to carry the infant around after meals or to arouse its interest by means of rattles or musical boxes is apt ultimately to exhaust both nurse and child. Strauch achieved success by the simple method of plugging the nostrils, since the resulting mouth-breathing renders it difficult to express the column of fluid into the pharynx. This succeeded perfectly in one of my cases, in the others it failed. It is further recommended that the infant should always be placed upon the abdomen after a meal. Others have endeavoured to prevent rumination by forcible closure of the mouth. A cap and a chin-piece are connected by two side-pieces of webbing, each bearing a buckle, and after the feed the mouth is held securely shut by tightening the side-pieces. This again has proved a successful device in some, but not in all the cases in which I have tried it. Probably the most uniform success has been achieved by thickening the child's food to the consistency of a thick gruel. I have used successfully farina boiled with milk until it was thick enough to adhere to an inverted spoon. In infants after the seventh or eighth month it is often sufficient to anticipate by a month or two the change to a mixed diet and to feed them as the normal child would be fed at the beginning of the second year. Rumination of this sort is prevented, or at any rate made much more difficult, when solid replaces fluid diet.

Finally, it is well to emphasize that in rumination, as indeed in almost all the conditions of habitual vomiting considered in this lecture, the personal factor of the nurse is of supreme importance. Rumination, like aerophagy, like the vomiting due to idiosyncrasy for cow's milk, and like the vomiting of nervous unrest, is found most commonly among infants of psychopathic inheritance and in a psychopathic environment. Isolation, handling by a competent self-confident nurse, the reduction of emotional disturbance to a minimum, are all of the greatest importance if recovery is to follow. The nervous disturbances of infants, like the infective disorders of infants, are apt to display themselves for the most part by symptoms referred to the sensitive gastro-intestinal tract. The infant has indeed but one function highly organized and therefore capable of showing complex disturbance—the function of digestion. It is in disorder of that function that throughout infancy nervous instability, inherited or acquired, especially shows itself.

I have to thank Dr. G. W. Nicholson, Professor Adrian Stokes, Mr. Redding, Dr. Lindsay Locke, and Dr. Vertue for their great kindness in providing me with the microscopic sections, microphotographs, and radiographs with which these lectures were illustrated, some of which have been here reproduced.

## TREATMENT OF INOPERABLE CARCINOMA OF THE CERVIX UTERI WITH RADIUM:

### DESCRIPTION OF THE MORE RECENT METHODS EMPLOYED.\*

BY

MALCOLM DONALDSON, F.R.C.S.,

ASSISTANT PHYSICIAN ACCOUCHEUR, ST. BARTHOLOMEW'S HOSPITAL;  
GYNAECOLOGICAL SURGEON, ROYAL NORTHERN HOSPITAL.

THE purpose of this paper is to demonstrate that the results of radium treatment in inoperable carcinoma of the cervix uteri are so promising that it is imperative that as many of us as possible should join in combined and organized research on these lines.

Medical opinion in this country is extremely sceptical of the value of radiotherapy, and I cannot help thinking that this is because so little systematic work has been done on the subject. I would ask the profession to keep an open mind, as much harm is done by the expression of very optimistic or very pessimistic views on a method which is, comparatively speaking, so new. Many people think of radium as a drug, of which there is only one dose and one method of administration, and that if this does not prolong the patient's life the treatment is of no value. Many years will elapse before we reach any final judgement on the value of radiotherapy, and meanwhile, in order to make progress, we must compare the value of the different techniques, not only as judged by complete cure of the patient, but also by lesser standards. These standards are: (1) histological; (2) rate of disappearance of symptoms, such as haemorrhage; (3) rate of disappearance of the local growth and healing of the malignant ulcers; (4) duration of the patient's life after treatment.

Next I would appeal to those working at this subject to make their reports on uniform lines, and, when mentioning the dose, to give the fullest details as to whether radium element is used or radium emanation, and, if the former, whether the number of milligrams relates to the salt or the element; the exact material and thickness of the filters; the form of the applicators; the exact number of hours during which the radium is applied; and as far as possible the distribution of the radium in relation to the growth. If emanation gas is used, additional notes should be quoted—namely, the number of millieuries at the commencement of the treatment and the number of hours. It is of little or no value to talk about milligram hours or even millieuries of emanation destroyed.

[The work here described has been carried out with radium kindly lent by the Medical Research Council.]

#### DESCRIPTION OF TECHNIQUES.

Speaking generally, there are two schools of technique—one which believes in external application only, the other which believes in burying the radium close to or within the growth. The arguments for the different opinions may be summarized as follows.

Those who advocate external application consider—

1. That any incision, even the introduction of needles, may disseminate the growth.
2. That the injured normal tissues may be affected by the radium to an undue extent, as it is well known that radium affects cells which are about to go into mitosis.
3. That the tissue extracts produced by injury to the normal cells may stimulate the growth of the tumour.
4. That the burying of needles may produce sepsis under conditions very suitable for the growth of organisms.

Those authorities who advocate the burying of needles do not consider that these objections are in any way comparable to the advantages of the greater intensity obtained by placing the needles near the growth, and, further, that if the radium is used from outside, the doses have to be so large that there is a considerable likelihood of damaging the skin and other intervening tissues. The Radium Institute of Paris is, on the whole, inclined to believe in external application. The Radium Institute of Brussels believes in buried radium. Most of the American institutes

\* A paper read before the fifth British Congress of Obstetrics and Gynaecology, London, April, 1923.

believe in buried radium, and some of them use unscreened glass tubes by means of which the beta rays are brought into action. The Radium Institute, Stockholm, believes in external application. Opinion in this country is divided.

**Vaginal Treatment by Surface Application.**—The usual routine is as follows: The vagina is prepared by means of douches, but the growth is not cauterized or in any way interfered with. One or more tubes are placed in the cervical canal, containing in all approximately 50 mg. of radium element, with a filter of 0.5 mm. of platinum. In the vagina there are more tubes, heavily filtered with 0.5 or 1 mm. of platinum, and sometimes these have additional filters of cork or aluminium and rubber, to stop the secondary rays coming from the platinum filters and to act as distancers. The amount of radium contained in these vaginal tubes is 25 to 30 mg. of radium element, making 75 to 80 mg. in all. The exact details of the filters vary in different clinics. The duration of application also is a matter of opinion, some authorities advocating twenty-four hours, others as much as a week or even more. On the whole the tendency seems to be to lengthen the duration of exposure.

**Extra-abdominal Application of Radium.**—In addition to vaginal application large quantities of radium are sometimes used on the surface of the abdomen, placed at a distance from the skin. This method has been widely employed in America, where as much as a gram of radium is used at a distance of 10 cm. As an example of burying technique by the vagina, I will describe my own method of treatment.

**Method.**—The patient is douched for two or three days before the operation with weak lysol. At the time of operation she is placed under an anaesthetic in the lithotomy position, and the vulva and vagina cleaned with pierie acid 3 per cent. in spirit. A microscopic section of the growth is then taken in every case in which the radium is applied for the first time. The needles are placed in and around the growth, keeping as far as possible about half a centimetre of tissue between each needle. The longer needles are pushed outwards as well as upwards into the base of the broad ligaments. The whole vagina is then packed with gauze soaked in flavine. The amount of radium I generally use is as follows: 8 large needles approximately 6 cm. long, each containing 3 mg. of radium element, filter 0.5 mm. of platinum; 12 or 13 smaller needles, each containing 2 mg. of radium element, filter 0.5 mm. of platinum; total number of mg. 48 or 50. These remain in place for 144 hours.

In my present series of cases the patient has a second vaginal application after an interval of four weeks.

**Technique for Intra-abdominal Radium.**—The great difficulty is to affect the deeper parts of the growth. With this in mind I carried out in one series the technique suggested by Daels of Ghent. This consists in putting the radium alongside the iliac glands, but extraperitoneal, and is carried out in the following manner:

The patient is put under an anaesthetic in the lithotomy position. An incision is made in the ischio-rectal fossa and blunt dissection carried out with the finger as far as the spine of the ischium. Another incision is made just to the inner side of the anterior superior iliac spine, and a blunt dissection carried out, the finger passing over the psoas muscle and external iliac vessels. A tube is then passed from the lower incision right through the pelvis to the upper incision, and through this tube a chain is guided, the tube being then removed and leaving the chain in place. One radium tube is attached to this chain, which is pulled on, and the desired depth can be obtained by counting the number of links of the chain remaining outside. The radium is moved each day, and entirely removed at the end of the third day.

This operation I carried out in 14 cases. Although some of these cases have done well I do not care for the technique, as it involves too much blunt dissection, and the radium is concentrated into one mass, and therefore does not conform with my ideal of uniform distribution throughout the growth.

The next method that I tried was that employed at the Radium Institute of Brussels—namely, the intraperitoneal method.

The patient is put in the Trendelenburg position and the abdomen opened. Needles are then placed in the back of the uterus and in the broad ligaments, and the rubber-covered wires holding them are brought out through the lower part of the abdominal wound. The whole pelvis is then packed with gauze (it generally requires about 8 yards of 6-inch gauze), and the end of the gauze brought out with the above-mentioned wires through the lower part of the abdominal wound. At the end of a week the gauze and wires are pulled out, the patient being given gas anaesthesia. I have performed this operation in ten cases.

Although some have done quite well I am not satisfied with the technique, and am at the present moment working out a new method, using a rubber plug to fill the pelvis.

**Combined Radium and X Rays.**—Until recently facilities at St. Bartholomew's Hospital for this method of treatment have been rather restricted, and my own experience of combining radium and x rays has been limited to a few patients treated in private by Dr. Finzi, two of whom have been very satisfactory indeed. Now that we have installed a deep x-ray plant purely for research we hope to undertake a large series of such cases.

**Conclusion regarding Technique.**—My own opinion is that any technique should aim at getting a comparatively small intensity evenly distributed throughout the growth, and applied for a comparatively long time.

#### DOSAGE.

The question of the best dosage is still *sub judice*. It is from the solution of this difficult problem that the final technique will be evolved.

Although it is impossible here to discuss in detail the physics of radium, yet there are one or two points to be remembered. The first of these is the fact that the intensity of radium obeys the inverse square law in the same way that light does. As an illustration it may be noted that the dose received by the fingers holding a tube of radium with a filter of 0.5 mm.

of platinum for half a minute is the same as if those fingers were exposed at a distance of one yard from the radium for a period of three and a half years; or, to put it in a more practical form, the tissues of the pelvis 2 inches away from the tube receive 10,000 times less irradiation than the tissues immediately surrounding it. In these circumstances, is it a matter for surprise that those people who only put one tube into the middle of the cervical canal do not prolong the lives of their inoperable cases? Another point to remember is the filter, which makes a considerable difference to the type of rays and intensity.

**Units of Dose.**—In order to understand the description of various techniques we must be quite clear about the expressions used to indicate units of dose. In using radium element in the form of a salt we should speak of  $x$  number of milligrams of radium element used for  $y$  number of hours, and then add the full description of the distribution and number of needles or tubes. When, however, emanation gas is employed the unit used is spoken of as a millicurie.<sup>1</sup> When emanation gas without its parent salt is used it breaks down rapidly, so that its activity declines by one-sixth every twenty-four hours. There are two ways of describing the dosage when emanation is used. We can say that the dose was  $x$  number of millicuries applied for  $y$  number of hours, and then work out by reference to a table the mean number of millicuries for the length of time of application. Or we can describe the number of

<sup>1</sup> When a milligram of radium is sealed up for a time the amount of emanation gas becomes constant, and this equilibrium amount is spoken of as one millicurie, and can be measured by its effect upon an electroscope.

Skigram of needles placed in position per vaginam. The shorter needles grouped in the centre are encircling the cervix. The longer needles on either side are in the base of the broad ligaments.

millicuries of emanation gas which have been destroyed during that time. For instance, if we put in 100 mc. and take them out after twenty-four hours, we shall have used approximately 16 mc. This latter method has the advantage that it can also be used for calculating the dose when radium element is employed. Whichever method is used it is still necessary to give details of the number of tubes, distribution, filters, etc.

*Dosage in Relation to Biological Effect.*—A great deal of work is being done in various laboratories to find out the exact action of radium on the normal tissues, and until the laws governing such action are known we clinicians can only grope about in the dark, trying by empirical means to find the most efficient dose. The first, and perhaps the most important, point to be decided is whether the biological results are proportional to the irradiation received; in other words, are the same biological results obtained by using 100 mg. of radium element for twelve hours as 50 mg. for twenty-four hours? That is, is it better to use a small dose for a long time or a large dose for a short time, or is it exactly the same thing? There is a certain amount of laboratory evidence that it is not the same thing, and in my opinion the clinical evidence is very much in favour of a medium dose, well distributed, applied for a very long time; in my last series of cases I have been using 50 mg. of radium element in twenty needles for 144 hours at a time, with distinct improvement in immediate results compared with my former series.

#### RESULTS.

The general public, and for that matter the majority of practitioners, will only judge results by the number of years the patient lives after the treatment, and although we all hope that eventually radiotherapy will be able to stand such a test in the case of inoperable carcinoma of the cervix, yet it is obvious that at first we must judge by the local and histological effects, for, as already mentioned, the more inaccessible parts of the growth go on living and continue to kill the patient as heretofore. That does not mean that radium has no effect on malignant disease; it merely means that we have not yet learnt how to apply it to the whole growth. My disinclination to judge the results of radium treatment by the years that a patient lives does not arise from a wish to vindicate radiotherapy. We at St. Bartholomew's took the matter up four years ago with absolutely open minds, and we judged the improvement or otherwise following the use of different techniques by:

1. The histological evidence from the uteri removed by hysterectomy following radium.
2. The rate of disappearance of symptoms.
3. The rate of disappearance of the growth and the healing of the malignant ulcers.
4. The duration of the patient's life after treatment.

#### Histological Evidence.

This histological work was all carried out by my colleague Dr. R. G. Canti. During the first two years of our research we paid particular attention to the histological findings after irradiation, and in two series comprising over 50 cases the amount of radium used and the technique were approximately the same, and we only changed the number of hours, the first series being for eight hours, the second for twenty-four. The conclusions that Dr. Canti came to were as follows:

- (a) That the introduction of approximately 170 mg. of radium element into and around the cervical tissue for twenty-four hours is capable of causing a complete disappearance of the growth in the cervix within a few weeks, whereas the same application for eight hours produces little or no effect in the quantity or appearance of the growth.
- (b) That definite series of changes in the carcinoma cells can be demonstrated after irradiation, leading up to complete destruction of the cell.
- (c) That little or no effect has been produced in affected iliac glands when the cervix is irradiated.
- (d) That as changes in the malignant cells take place before the formation of fibrous tissue, the latter is not the causal agent in the disappearance of the growth.
- (e) That the carcinoma cells are more vulnerable than the uterine musculature, but in the latter local atrophy and fibrosis take place at a later date.

In one case, in which hysterectomy was performed as early as four weeks after the first application of radium, no growth was found in spite of a number of sections being cut and examined, and in the other hysterectomies (some of them performed at the end of a week, others after several weeks), if growth was found at all it was so affected as to make it impossible to believe that the cells would have been viable.

#### Disappearance of Symptoms and Signs.

In order to get the most reliable symptoms and signs by which to judge the effect of irradiation, we have chosen the three following: (a) haemorrhage; (b) ulceration; by this we mean malignant growth of an ulcerative type, in contradistinction to (c) the proliferating cauliflower type of growth.

An analysis of these symptoms and signs shows the following: Of 85 cases treated, all were quite inoperable except 11. Of these 11, 5 were borderline cases upon whom some people would undoubtedly have attempted operation, 6 were cases upon whom I myself would have operated had it not been for the general condition, or the fact that the patients themselves refused operation.

(a) *Haemorrhage.*—Of the 85 cases, in 5 no note was made of the symptom of haemorrhage after treatment. Of the remaining 80, in 68—that is, in 85 per cent.—haemorrhage ceased, either permanently or for a considerable time, which in itself is of benefit to the patient.

(b) *Ulceration.*—Of 68 cases in which ulceration was noted before treatment started, and in which a note was made concerning this condition after treatment, it was found that ulceration had disappeared entirely, either temporarily or permanently, in 45 cases—that is, in 63 per cent. In 23 cases ulceration did not disappear. In these 23 cases, as a matter of fact, it diminished for a time in some, but as the question of the size of an ulcer is always a matter of opinion this is not taken as any index.

(c) *Growth.*—In 37 cases in which growth (by this is meant the raised cauliflower type of growth, in contradistinction to malignant ulceration) was noted before treatment, this entirely cleared up in 26—that is, in 70 per cent. In 11 cases it did not disappear entirely, although in some it was diminished.

It was noted that both these last signs—malignant ulceration and malignant overgrowth—disappeared more quickly in those cases which had had applications of radium for long duration.

#### Duration of Life.

The figures relating to the cases treated at St. Bartholomew's Hospital are as follows:

Of 85 cases treated between May, 1921, and April, 1925, 74 were hopelessly inoperable, 5 were borderline, 6 operable but for various reasons were not operated upon, as already mentioned. Of these 85 cases, 31 are living and 54 have died. As, however, some of these living cases have only been treated for a few months, the real facts are better expressed by taking those cases which were treated between May, 1921, and May, 1924.

Of 58 inoperable cases, 10 are living after one year or more—making 18.9 per cent. Of these 10, 1 has lived for 48, 1 for 43, 1 for 40, 1 for 21, 1 for 19, 1 for 17, 1 for 14, and 3 for 12 months.

Of 4 borderline cases treated, 1 has lived for 16 months. Of 2 operable cases treated within the same period, 1 has been living for 12 months. Taking these three classes comprising 64 patients, there are 12 living for 1 year or more—making 18.7 per cent.

Of the 54 cases who have died, 14 lived for one year or more, 1 lived for 36 months, 1 for 31 months, 1 for 26 months. All the 14 were very materially benefited for a considerable time, and there is very little doubt that their lives were prolonged. Of the remainder 27 were benefited and made more comfortable. Of time, but there is no evidence that their lives were prolonged. Of the rest, to 8 the treatment seemed to do no good whatever, and in the case of 5 it is quite possible that it actually did harm. Of the 64 patients, therefore, all but 13 received some benefit—making 80.9 per cent.

Of the 21 patients living less than a year, 4 are doing badly and going downhill; the rest appear well.

It is impossible to quote all the statistics available, but the following figures give some idea of the prolongation of life in some of the well known centres.

Last year the Radium Institute of Paris published the following figures. Of those cases treated in 1919, 1920, and 1921, 226 cases of carcinoma of the cervix were treated solely by radiological methods. Of these—

Of 21 cases of recurrences following operation, 2 are free from recurrences (one was treated with x rays as well), 3 are living but have recurrences, 16 are dead. Professor Régnaud dogmatically states that a preliminary hysterectomy causes radium therapy to lose all the anatomical conditions for its efficacy, and moreover is liable to scatter malignant cells, and is therefore a great mistake.

Of 114 inoperable cases, 15 appear to be without any recurrences, the longest being three and a half years and the shortest one year. This equals 13.2 per cent.; 12.4 per cent. were greatly benefited.\*

Of 67 borderline cases, 24 are still living, the time since the beginning of treatment varying from one year to three and a half years—making 35.8 per cent.; 35.8 per cent. were greatly benefited.

Of 24 operable cases, 11 (45.8 per cent.) are still living without any sign of recurrences, for times varying from one to three and a half years. In another 25 per cent. the disease disappeared locally.

The statistics published by the Radium Institute of Brussels are roughly as follows:

**Operable Cases.**—Of 14 operable cases treated by radiotherapeutic methods, 75 per cent. were living and free from signs of growth at the end of one year or more.

**Borderline Cases.**—Of 24 doubtful cases, 12 were free from any signs of growth after one year or more—making 50 per cent.

**Inoperable Cases.**—Of 24 inoperable cases, 8 per cent. were living and free from any sign of growth after one year or more.

The figures from the Radiumhemmet, Stockholm, are:

Of the 181 inoperable cases treated, 16.6 per cent. were well after five years.

Of the 36 operable and borderline cases, 40.5 per cent. were well at the end of five years.

The following list shows the number of cases treated in various years at the Memorial Hospital, New York, and the number living in May, 1921.

## RADIUM TREATMENT OF INOPERABLE CARCINOMA OF THE CERVIX†

BY

GILBERT I. STRACHAN, M.D., M.R.C.P.,

F.R.C.S. (ENG. AND ED.),

ASSISTANT GYNAECOLOGIST, CARDIFF ROYAL INFIRMARY; FIRST ASSISTANT TO THE PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE.

THIS communication is founded on a study of 40 cases of carcinoma of the cervix treated by the application of radium. The radium is supplied to the Cardiff Royal Infirmary by the Medical Research Council for research purposes, and inoperable cases of this disease have been treated in this manner since May, 1922.

### Technique of Application.

The dose usually employed is 150 mg. of radium bromide, and it is inserted for twenty-four hours. Two tubes of 50 mg. each, sheathed in 2 mm. of platinum, are inserted into the cervical canal, and the others are distributed at the periphery of the growth according to the anatomical conditions. In some cases six tubes of 10 mg. each are inserted in a circle, but in other cases, when the condition is of irregular shape, the smaller tubes are inserted where they would appear to be most effective.

Difficulties may be met with during application. In a number of cases the cervix had ceased to exist as a protrusion into the vaginal vault, and was represented by a foul, bleeding, friable ulcer, and in these it was often very difficult to get a satisfactory grip of the friable material with a volsellum. In some cases the cervical canal was difficult to find, especially where the growth was hard and excavated. It is essential, however, to find and explore the canal with a sound to exclude the presence of an unsuspected pyometra. This condition was present in 12 cases, in none of which was there any pyrexia or marked uterine enlargement. If pyometra be found the cervix should be dilated and the uterine cavity drained before radium is applied. In the cauliflower type of growth and in some others showing exuberant fungation the cervix is scraped prior to the insertion of radium. In such cases the radium should be inserted immediately after scraping, so as to prevent dissemination of the carcinoma cells.

After removal of the radium a vaginal douche should be given, and repeated night and morning for three weeks. This is recommended by Hayward Pinch, and is a practical necessity in the prevention of adhesive vaginitis, which developed in certain cases where douching was omitted and rendered future applications and investigation very difficult.

At the first and each subsequent insertion a specimen of the growth is obtained for microscopic examination. As the condition improves it becomes progressively more difficult to fix the cervix, to get a proper view, and to remove a piece for examination, as, in the process of "healing," the carcinomatous cervix becomes more and more retracted up into the vaginal vault until only a little cicatrized area is present there, with the vaginal walls often slack below it.

**Contraindications.**—The main contraindications to the use of radium may be classified under these headings:

1. The presence of pyometra. This is discussed above; drainage is required before radium is introduced.
2. The presence of inflamed appendages. Radium is apt to set up an acute exacerbation in such cases.
3. Vesico-vaginal fistula. If this is present when the case is first seen radium is inadmissible, as an acute cystitis may be set up. If fistula develops in the course of treatment no further application should be given.

### Histological Changes.

The histological changes in the carcinoma cells were at first puzzling and difficult to interpret; but after familiarity with the appearances had been acquired the changes were found to be of a more or less uniformly degenerative character in a large number of sections examined at different periods after treatment.

The first change observed was enlargement of the cells and of the nuclei. It was found in a number of cases as early as the third day, and usually by the end of the first week. In the majority of cases the cell cytoplasm and nucleus did not take up the stain as deeply as before. Here and there atypical karyokinetic activity was seen, shown by splitting of the chromosomes, often in an irregular manner. Oedematous infiltration was seen in the stroma; the changes in both situations were attributed to oedematous swelling due to a vascular reaction to the damage caused by the radium. True degeneration was usually well marked by the end of the second week. The nucleus was affected first; karyokinetic changes were no longer seen, the definite nuclear structure was lost and it stained darkly, showing little or no structure, and having an indefinite margin. The cytoplasm of the cell also underwent granular degeneration, and vacuolation occurred, while the cell walls stained faintly. By the fourth week degeneration was well advanced and the nuclei had either disappeared or were represented by dark structureless masses in the interior of the cells. Degeneration of the cytoplasm had also advanced; it stained irregularly, and vacuolation was well marked. In some cases what was left of the nucleus was seen to be pressed against the cell wall by a vacuole which occupied the rest of the cell. The cell walls were very faint or indistinguishable, so that areas were seen here and there occupied by an irregularly stained mixture of degenerated cytoplasm and nuclei with vacuolation—almost the appearance of degenerated syncytium. At about this period the stroma began to show reaction. Around the epitheliomatous columns lymphocytic infiltration was marked, together with an increase of vascularity and a return of oedema.

These changes progressed until about the sixth week, after which little more effect on the carcinoma cell was to be expected as a result of a single application. The reaction of the stroma now became the main feature, and in time a condition of fibrosis was brought about; it did not occur until the cellular degeneration was advanced, and is to be regarded as a process of repair bringing about what amounted to scar formation. In some

\* In 1919 and 1920 every single case that could reach the institute was treated. Since then the inoperables have been selected slightly, as it was found that when very far advanced the treatment did more harm than good. The authors consider that x-ray treatment only is better for these cases than radium.

† A paper read before the Fifth British Congress of Obstetrics and Gynaecology, London, April, 1923.

sections this fibrosis was universal and no remains of carcinoma cells were to be found, but in the great majority of sections taken as long as one year after infiltration lighter staining areas were seen occupied by the debris of cells and representing the degenerated remains of columns of carcinoma.

The stroma remained infiltrated with lymphocytes in the areas surrounding such masses of debris usually for several months. While these degenerative changes were well marked and easily observed, it was remarkable how fragments or debris of the carcinoma cells persisted even in cases showing clinical cure.

#### *Clinical Changes.*

The clinical changes were usually well marked, and consisted of all degrees of improvement of the three main symptoms—haemorrhage, pain, and discharge.

*Haemorrhage* was the symptom most completely controlled. Usually it ceased within the first ten days, and, in a case reacting satisfactorily, either did not recur or only an occasional slight loss occurred. This often happened even when subsequent physical examination showed some persistence of ulceration which might bleed on manipulation.

*Cessation of discharge* occurred in 18 cases, but in 6 others it was considerably diminished. It was usual for a patient to state that the bleeding had ceased and that she now had only a little discharge.

*Pain* was affected variously. In about one-third of the cases it was entirely relieved, in another third partially relieved, and in the remaining third either unaffected or aggravated. It is probable that such aggravation is due to pelvic fibrosis compressing the nerves, in spite of the fact that the majority of such cases showed clinical improvement and increased mobility of the uterus.

On *local examination* marked changes were found. Usually by the end of the first month the ulcerated surface had cleared up considerably, and in another month the improvement was such that ulceration had disappeared and the cervix was represented by a cicatrized dimple at the vaginal vault. By this time also the periuterine infiltration had usually cleared up, and a uterus which, at the first examination, was found to be firmly fixed was now more or less mobile with the thickening dispersed from the fornices. This would show that at least a certain amount of such pelvic infiltration is inflammatory.

#### *Results of Treatment.*

The following is a summary of the results of treatment in this series.

Of the 40 cases, 26 had one application of radium, and of these 3 are known to have died within a year, 4 failed to report again, and 2 developed vesico-vaginal fistula. Of the remaining 17 cases the clinical improvement in symptoms and on examination was so marked as to constitute clinical cure in 10; while in the remaining 7 discharge and pain have persisted in 5, with haemorrhage in 2, and the local condition shows unsatisfactory healing and some persistence of infiltration.

Ten cases had two applications of radium, and of these 2 died and 6 failed to report. The other 2 both showed marked local, general, and symptomatic improvement, being free of symptoms with the local condition cleared up beyond recognition and with increase of weight.

In 3 cases three applications were given, and one of these failed to report. The other 2, when last seen, were free of symptoms and the local condition was represented by a cicatrix in the vaginal vault.

In one case, in which carcinoma of the cervix developed subsequent to previous subtotal hysterectomy for a uterine fibroid, four applications of radium have been given; symptoms have ceased and the local condition has cleared up.

Of the 40 cases, then, 5 are known to have died and 11 have failed to report; vesico-vaginal fistula has developed in 2, and in 7 the clinical condition is unsatisfactory. Considerable improvement, amounting to clinical cure, has been obtained in 17 cases. It appears reasonable to estimate that of the 11 cases who failed to report 6 have died; on this estimate the total number of deaths would be 11, while if the whole 11 are to be counted as dead the total deaths would be 16.

The number of cases actually treated by radium is in excess of the 40 quoted, but none are included whose treatment commenced less than a year ago.

#### *Conclusions.*

The conclusion arrived at is that in inoperable carcinoma of the cervix we have in radium the most potent therapeutic agent yet to hand; that in practically all cases greater or less alleviation of the haemorrhage and discharge can be obtained; and that in slightly under 50 per cent. a condition of clinical cure is brought about. The action of radium is locally destructive to the carcinoma cells and produces such degenerative changes that further activity would appear to be out of the question. The line of further investigation is therefore by improved technique and, if necessary, by increased dosage to expose all parts

of the parent tumour, together with any extensions, to the fullest effect of the radium rays so that cell activity may cease.

It is to be emphasized that this paper represents essentially a personal experience which happens to be in general accord with the experience of others who have used radium as a palliative in carcinoma of the cervix.

The cases considered were all inoperable according to the usual clinical criteria, and such controversial aspects of the matter as radium as an alternative to operation in any given case, preliminary radiation in the so-called borderline cases, or post-radiation hysterectomy in cases showing such local improvement and disappearance of infiltration as may tempt the surgeon to operate, have been avoided. Again, all the cases recorded were treated locally, and no attempt was made to treat extensions in the pelvis, as by the Dachs and Schwartz operations. The recorded results of these procedures have not tempted me to resort to them.

It is important to estimate the exact position that radium should occupy in the treatment of carcinoma of the cervix, and it is as a contribution in that direction that this paper is presented.

I am indebted to Professor Sir Ewen Maclean for putting beds at my disposal for this investigation.

## THE APPLICATION OF ULTRA-VIOLET LIGHT IN GENERAL PRACTICE.

BY

T. CLYDE MCKENZIE, M.B., Ch.B.,  
SMITHWICK, BIRMINGHAM.

At the present time much is being written on the specialized application of ultra-violet light, but to my knowledge nothing has been recorded of its use in general practice.

As a result of six months' experimental work on friends and myself with various types of lamps, I selected a quartz mercury vapour lamp\* of the atmospheric type. Such a lamp has the advantage of portability, and combines economy of current with powerful ultra-violet radiation. The expense of producing the light is not prohibitive, for the electricity used does not cost more than the average bottle of medicine.

The actual source of the ultra-violet light is the gaseous particles of mercury raised to a point of incandescence by the passage of an electric current. This constitutes the mercury arc. Until recently the only type of mercury vapour lamp was the vacuum lamp, but the atmospheric pattern I have used is much stronger in ultra-violet radiation and has a longer effective life. It is important to add that it is necessary at all times to guard the eyes by glass goggles, since the ultra-violet light causes severe conjunctivitis unless such protection is used. Once installed, the lamp appears to be indestructible, except by mechanical breakage. I have had one in use for over 2,000 hours and it is apparently as good as new.

Various tests have been devised for measuring the intensity of ultra-violet radiation. Amongst others, the bleaching of methylene blue (L. Hill) and the toxic property of ultra-violet light on bacteria introduced into the blood stream (Eidinow). The methylene-blue test, however, is of use only for indicating comparative strengths of ultra-violet light and does not determine the reaction of the individual. The blood test, useful in measuring the effect on the patient, is somewhat difficult to perform in general practice. A simple preliminary test can be made by exposing a small area of the palmar surface of the patient's forearm to the light for one minute at a distance of 6 inches. The resulting erythema is noted after twenty-four hours.

I would emphasize the fact that in 90 per cent. of the following cases I had previously tried ordinary therapeutical measures which were either ineffective or progress was extremely slow. Details given below are of my early cases when I used a 110-volt lamp. Lamps can now be obtained

\* Such a lamp is manufactured by Messrs. Kelvin, Bottomley and Baird, in their works at Hither Green, S.E.13. A suitable stand was designed for me, and has proved very satisfactory for applying local and general irradiation.

up to 440 volts. The room temperature was maintained at 70° to 75° F.

**Ulcers.**—All cases treated have responded after varying periods; one worthy of note was a blacksmith's striker, who did not lose a day's work while undergoing treatment. The following is a typical case: Indolent ulcer of six months' standing in a girl aged 17. After nine weekly irradiations, beginning with three minutes at a distance of 10 inches and increasing to fifteen minutes at 6 inches, the ulcer was completely healed.

**Eczema.**—Exposure to the lamp produces very rapid reaction; at first the itching and discharge is increased, but this quickly gives way to new skin formation and complete relief from pain and irritation. A typical case was that of a cabinian with severe eczema of the right leg who had been treated medicinally for some weeks with no good result. His leg was irradiated weekly, beginning with five minutes at 10 inches. After seven treatments, finishing with ten minutes at 6 inches, the leg was healed.

**Alopecia Areata.**—Cases of this disease have been successfully treated after medicinal measures had failed; hair 1 inch in length may be seen six months after treatment. Healthy hair grows about 4 inches a year. Prolonged treatment is not always required. Fine hair often appeared on bare patches after the third treatment. In a typical case, in a woman on whom a patch of alopecia areata had existed on the back of the head for six months, I began with fifteen minutes at 12 inches. Four irradiations at intervals of 1 fortnight at a distance of 6 inches for fifteen minutes were sufficient to start the hair growing.

**Sycosis.**—In this disease both successes and failures must be recorded. A chronic case healed, but three weeks later broke down: this may have been due to the fact, which I discovered later, that he was using his old shaving-brush. On the other hand, a case of sycosis of the upper lip responded rapidly and healed after four treatments. A case which may be quoted as typical is that of a man, aged 52, whose upper lip had been infected for several weeks. The lip was irradiated on four occasions at a distance of 2 inches, commencing with three minutes and increasing to six minutes. Two sun-baths of the body were also given.

**Lupus.**—Three instances of lupus have come under my notice in the past twelve months. All made excellent progress under the treatment. One has healed, the others are approaching that condition. These patients have had weekly irradiations.

**Burns** heal very quickly as compared with ordinary medical treatment, often showing healthy epidermis in half the time usually required.

**Psoriasis.**—I feel diffident about mentioning this disease, but results would appear to show that ultra-violet radiation is very valuable in the treatment of this disorder. Local patches are rapidly removed, but where the disease is general a long course of treatment is essential.

**Sciatica.**—Six to twelve treatments would appear to give complete relief; even long-standing and acute cases respond; one patient who had been fourteen weeks in bed returned to work after six irradiations. One case only was unrelieved—a man, aged 63, who had been ill for six months. He, however, had only three treatments. A typical case is that of a man, aged 37, who had had sciatica of the left leg for fourteen weeks. At the first exposure he was given three minutes at a distance of 5 inches; the pain was relieved. Six other irradiations were given at weekly intervals, the time being increased to fifteen minutes at the same distance.

**Local Tuberculous Conditions.**—Tuberculous knees, glands, and hip, and an anal abscess have all responded to treatment. A patient with a tuberculous hip who has been a cripple for eight years is already, after six irradiations, walking and able to go out alone, which she had not attempted to do for three years.

**Chorea.**—I have found the ultra-violet radiation very useful in the treatment of chorea. A patient had had the disease for five consecutive years, often being confined to bed for as long as three months. She had weekly sun-baths, and was kept up and about last year, although pregnant. At first she was given small doses all over the body; and later the dose was increased until she could stand as much as an hour at a time. Whenever the chorea appeared to be starting extra baths were given. She bore a strong healthy child, although she had miscarried twice previously.

**Rickets.**—Children with rickets always respond well to ultra-violet radiation. One child who, on an average, was having fits twice a week, due to the disease, has not had a return since its first sun-bath. In another case—a male child aged 5 months—I began with five minutes' radiation over the body at a distance of 18 inches. The bath was repeated twice a week, the time being gradually increased to fifteen minutes. He was treated for three months.

**Rheumatism.**—The chronic rheumatic patient appears to derive considerable benefit from ultra-violet light; it certainly seems to relieve rheumatic patients of pain and stops the progress of rheumatoid arthritis.

From the above cases it may be concluded that ultra-violet light is not only useful to the tuberculosis and child welfare medical officers, but also to the general practitioner in his daily work. The form of apparatus I have used can be fitted comparatively easily in any surgery, and, provided the doctor gives his personal attention and exercises considerable patience, he will soon obtain good results.

Ultra-violet light is by no means a panacea for all ailments, and in some of the diseases I have treated it simply replaces a more painful and cumbersome method by a pleasant and easily applied remedy. I think also that it often acts quicker than some of the older methods, allowing

patients to go on with their work or return earlier to work than otherwise. Especially do I recommend it to the practitioner in an industrial area where the worker, hidden between walls or under glass all day, is hardly ever subjected to the ultra-violet rays of the sun, and is therefore more susceptible to ultra-violet action.

There is little doubt that a general sun-bath stimulates the average person if it be given wisely. In my opinion, on no account should a patient be allowed to treat himself, as I have seen some very bad effects from overexposure. The artificial sunlight bath appears to act on the general metabolism of the body—the appetite improves and the mental outlook brightens. This is particularly the case, of course, in large towns and industrial districts such as that in which my own practice lies. During the winter months I find it a most valuable asset.

## ACCENTUATION OF A "MITRAL MURMUR" BY A TEMPORARY TOXAEMIC CONDITION (ACCOMPANIED BY TEMPORARY NYSTAGMUS).

BY

G. ARBOUR STEPHENS, M.D., B.S., B.Sc.,  
CONSULTING CARDIOLOGIST, KING EDWARD VII WELSH NATIONAL  
MEMORIAL ASSOCIATION.

THE patient in this case was a boy, aged 14 years and 10 months, an indoor pupil of the Royal Cambrian Institution for the Deaf and Dumb. His deafness is congenital, and it may be of interest to state again that nearly all cases of congenital deafness have hearts with normal sounds, whereas the majority of acquired cases have some adventitious cardiac sounds. My experience is that the acquired cases are generally associated in their origin with some specific feverish condition, when either through some inflammatory condition of the heart the circulation of the blood in the region of the middle ear becomes enfeebled, or through some coinciding inflammation of both heart and ear the local tissues are irretrievably damaged.

For such a reason it may be of interest to mention that when this boy, in March, 1918, at the age of 8, was first medically examined by me his heart sounds were normal, but when I re-examined him in March, 1919, he had what is usually called a systolic mitral murmur. Between these two examinations (namely, in November, 1918) he had a very bad attack of influenza. The mitral murmur at each periodical examination did not become more marked, but rather seemed to be, if anything, less noticeable. Slight distinctions in quality and quantity of heart sounds are, however, very difficult to estimate. At any rate, he did not suffer at all from an impediment to the circulation of his blood, and his activities were quite unimpaired.

On December 19th, 1924, there was a Christmas tree at the institution, when this boy indulged unduly in the good things on the table. About an hour after the feast was over he fell down, and was thought to have hit his head. He became pale, pulseless, and collapsed, and the stomach was emptied of all its contents. Before I arrived he had been given a small quantity of brandy, but neither this nor any water could be retained. When I examined him there was no evidence of any cut or bruise on the head, nor did there appear to be any soreness on the following days. He was quite unconscious, the pupils were considerably dilated, and he had marked lateral nystagmus. The temperature was 100° F., and the pulse (120) was very soft and feeble. I found a very diffused impulse beat, a slight increase of the cardiac dullness, and a marked mitral murmur over the whole cardiac area. As he was quite quiet and in no pain, with only a very slightly raised temperature, I ordered him to be kept warm with hot-water bottles, and watched during the night.

The next morning some amount of consciousness had returned, the nystagmus was less marked, the pulse slightly stronger, but he was still very pale and the tongue flabby. The heart's impulse was still considerably diffused and the murmur very marked. He was ordered 3 grains of calomel (which had the desired effect), and subsequently was given three drops of Condy's fluid in water every four hours. In two days the nystagmus had disappeared, the pulse tone was restored, the tongue and appetite were good, whilst the impulse was nearly normal. The next day he was allowed to be taken home for the holidays, with a note as to the condition of things to the medical officer of the education authority.

After his return from the holiday (when the treatment consisted entirely of rest) I found the heart conditions normal, save for a slight mitral systolic murmur, and the reserve power of the heart good, whilst there was no evidence of any nystagmus.

The presence of this temporary nystagmus is of considerable interest and importance, for in my opinion it helps to emphasize the toxæmic nature of the whole attack—the nystagmus, like a vertigo, arising from some gastric poison. The collapsed and pulseless condition can be considered due to a toxæmia, whilst the stomach disturbance, together with the beneficial result obtained by means of calomel, seems to confirm a gastric origin. Gastritis of such a nature is usually associated with signs and symptoms classified under the head of urticaria—an irritable condition of the skin resulting in rapid exudation of serum or lymph; an acute labyrinthitis causing vertigo; an acute injection of the bronchial mucous membrane causing asthma.

In this case there was a markedly diffused impulse and an extensive accentuation of the mitral systolic murmur. This marked diffusion of impulse is explainable by a rapid exudation of fluid into the pericardial cavity, which accounts also for the increase in the area of cardiac dullness. That this pericardial fluid is subject to variations needs no proof, but to prove definitely when and to what extent those variations occur we have to fall back on symptoms. Any disturbance of the intrapericardial conditions is necessarily associated with very alarming symptoms, and of such a nature as was found in this patient.

Normally one finds 4 to 8 c.cm. of pericardial fluid present post mortem, generally lying in the most dependent part of the opened sac, but that is no evidence of the position or conditions of the fluid during life. In 1915 I drew attention to the fact that during life the intrapericardial pressure is negative to the extent of 6 to 8 cm. of water, and the result of this negative pressure is by suction action to keep the pericardial fluid at an equal thickness all over the surface of the heart.

For an organ like the heart, in, as it were, perpetual motion, a great essential is proper lubrication, which is supplied by the pericardial fluid, right both in quality and quantity; but should a toxæmic condition occur suddenly, with a rapid exudation into the pericardial cavity, the lubrication is disturbed and the motion of the heart interfered with to a serious extent. Evidence of such an exudation into the pericardial cavity is supplied in the case here recorded by the markedly diffused cardiac impulse.

Heart disease has been recognized as an entity for barely one hundred years, so that whatever tradition exists cannot be above criticism, especially of a constructive nature. In my opinion a great wrong has been done to the science of cardiology by depicting on cardiograms the "exact" position of a sound or murmur, implying a scientific exactitude for what is really a matter of individual judgement.

Let us for the moment cease to consider the cause of the heart sounds, and concentrate on the conditions necessary for their conduction to our auditory apparatus. The heart sounds have to pass through the pericardial fluid (normally a thin layer) as well as the chest wall. With a rapid exudation of fluid into the pericardial cavity there must be a considerable modification of the conducting conditions, to prove which one need only refer to the fact that in a case of marked pericardial effusion the heart sounds are not heard. Since fluid is a good conductor of sound we should expect the heart sounds to be readily transmitted, but the reverse is proved to be the case. The "energy" transmitted from the chestpiece of a stethoscope to the ears is the same as that transmitted from the chestpiece of a cardiograph to the tambour and "pen" for the production of the heart curves or waves on the moving roll of paper. The "heart curves or waves" therefore represent on paper what is heard by the ear—that is, the "heart waves" represent the heart sounds.

In pericardial effusion the "heart waves" are reduced to a minimum, and so also are the heart sounds; in other words, there is so little movement of the pericardial fluid that no movement is recorded on the cardiogram.

Is the diminution of this fluid motion associated with the disappearance of the heart sounds? Were the sounds produced in the heart they would be conducted all the more readily with such a large quantity of fluid: in other words, are the heart sounds produced normally by the fluid in the pericardial cavity?

Watson, to whom belongs the credit of being a pioneer in the realm of cardiology, dogmatically asserts that the first sound of the heart is due to the contraction of the heart muscle—"because, gentlemen, you all know," he tells us in his lectures, "that a muscle when it contracts produces a sound." But a muscle when it contracts produces no sound, so that the heart sounds cannot be due to the contraction of the heart muscles. The vibration of the valves has been asserted to be responsible for many heart sounds, but is it possible to believe that a thin membrane, of which the valves are composed, can be strung so taut as to cause such a loud-sounding vibration as evidenced by the heart sounds? Truly, when the valves are affected the sounds are affected, but the more diseased the valves the less they are capable of vibration, although coincident with a marked increase in volume of sound. When, however, the valves are affected the intrapericardial conditions are also considerably modified, and I have drawn attention to the fact that in heart failure the intrapericardial pressure has become atmospheric with a consequent loss of suction action whereby the lubrication of the heart is greatly disturbed.

It is now generally agreed that the end comes in heart disease, not by valve leakage, but through failure of the myocardium, which to act satisfactorily must be properly lubricated with pericardial fluid of the right quality and quantity under proper conditions; but, as I have proved by means of the manometer, those pericardial conditions are not normal in death due to heart disease.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### GALL STONES IN A GIRL AGED THIRTEEN:

##### CHOLECYSTOTOMY, REMOVAL OF FOUR STONES: RECOVERY.

The memorandum by Dr. R. S. Woods (*BRITISH MEDICAL JOURNAL*, March 21st, p. 552), describing cholecystectomy in a male aged 18, has stimulated me to record this case:

I have not attempted to search the literature, but Walton (*Annals of Surgery*, July and August, 1911) gives the following table showing the age at time of operation in the 409 cases upon which his paper is based, and the ages at which symptoms first appeared.

Age at Time of Operation.		Age at which Symptoms Appeared.	
Age.	Number.	Age.	Number.
1-10	0	1-10	3
11-20	0	11-20	27
21-30	26	21-30	57
31-40	68	31-40	122
41-50	117	41-50	101
51-60	123	51-60	67
61-70	63	61-70	27
71-80	11	71-80	5
81-90	1	81-90	0

He quotes a paper by Still in which records of twenty-three cases in young children (ten of them stillborn and young infants) are collected. Nevertheless, the operative removal of gall stones at the age of 13 must be sufficiently rare to be of interest.

I was asked to see a girl, aged 13, in consultation. Her doctor informed me that some months previously she had had cystitis accompanied by *B. coli*. For about eighteen months she had had frequent attacks of severe abdominal pain and vomiting. These attacks usually came on at night. She had had an unusually severe attack starting at 2 a.m. on March 21st, 1920. When I saw her on the afternoon of March 23rd, the pain, now much less severe than it had been, had settled in the right hypochondrium and right iliac fossa. The abdomen was normal except that the right lower rectus was somewhat rigid.

I diagnosed recurrent appendicitis. As the present attack had subsided I arranged to operate, and on March 27th, 1920, opened the abdomen, using Battle's incision, and removed the appendix. It contained a concretion and two threadworms, and showed a stricture near the tip. As, however, it was hanging down in the pelvis I was not satisfied that it accounted for the pain in the hypochondrium. I therefore explored further and found to my surprise a large gall bladder containing stones. I enlarged the incision, opened the gall bladder, and removed four large stones.

No stones were felt in the ducts. The gall bladder was drained and the abdomen closed. The stones were roughly round, but showed from one to three well marked facets on each. The diameter of the smallest was one-third of an inch, of the largest half an inch. They were of the laminated bile pigment and calcium type.

The patient made an uneventful recovery and left the nursing home quite well.

PLYMOUTH.

### ULTRA-VIOLET THERAPY.

THERE are still so many gaps in our knowledge both of the theory of ultra-violet therapy and of the physiology of the suprarenal glands that, at the risk of calling attention to a phase of their relationship which may have already been recorded, I venture to send the following note:

M. H., male, aged 12½, has suffered for nine years from attacks of bronchial asthma of moderate severity, induced apparently by errors of diet, cold, erupting teeth, fatigue, and excitement. Many forms of drug treatment have been tried without success, until quite recently, when adrenaline was tried and found to act as a specific. He had his first dose of light (two minutes' exposure to K.B.B. air-cooled lamp at 14 in.) at 7 p.m., and developed an attack of asthma early next morning. At 9 a.m. he was given a dose of adrenaline and it was noticed that the erythema was much less developed in him than in his younger brother, who had received the same dose of light at the same hour. Within half an hour the asthma had passed off, and at 12.30 he remarked that his skin was itching a good deal; the erythema was found to be that of a mild second degree, little if anything less than his brother's.

It appears to be a reasonable deduction that the skin's reaction to light makes a demand upon the suprarenals, which in this case temporarily exhausted them and thereby induced an attack of asthma; and that the small dose of adrenaline relieved the latter and enabled the reaction to be completed. Incautious exposure to sunlight of patients with active tuberculosis is well known to induce exhaustion and rise of temperature, but these effects have generally been attributed to the heat rays. This case strongly suggests that a truer rationale of the reaction would attribute the effects to suprarenal exhaustion, and affords a reasonable prospect that adrenaline, given at the time of an exposure to light, would safeguard these patients from such untoward results, just as it does in the case of M. H. At the same time it explains the good results claimed for the ultra-violet therapy of high blood pressure.

London, N.6.

### JEJUNAL ULCER.

IN view of the recent correspondence as to the advisability of performing gastro-enterostomy at the same time as closure of a perforated duodenal ulcer, the following case would seem to be of some interest.

G. V., an iron-worker, aged 41, had been suffering from abdominal pain for eight months, when he underwent an operation for perforation of a duodenal ulcer in May, 1923. The surgeon who operated, besides suturing the perforation, performed posterior gastro-enterostomy. Recovery was uneventful.

For three months the patient did well, but after that time he began to complain of severe pain, and to lose weight. He was first seen by me in August, 1924. X-ray investigation showed both the pylorus and the gastro-enterostomy orifice to be functioning. He was seen in consultation by Dr. A. E. Barnes of Sheffield, who diagnosed jejunal ulcer. I operated in March, 1925, and found a large indurated jejunal ulcer, the crater of which was as large as a halfpenny, the base being formed chiefly by the transverse colon. The ulcer perforated as soon as the manipulation was begun. The ulcer was excised with the first eight inches of the jejunum, the opening in the stomach closed after excising the indurated parts, and the divided jejunum joined end-to-end with the duodeno-jejunal flexure. The pylorus was found to be quite patent, and there was no sign of the former duodenal ulcer. Recovery has, so far, been satisfactory.

It would appear to be a fair assumption that if suture of the perforation had alone been carried out at the first operation in this case the patient would have been saved the necessity of further interference.

Honorary Surgeon, Rotherham Hospital.

## British Medical Association.

### CLINICAL AND SCIENTIFIC PROCEEDINGS.

#### BRIGHTON DIVISION.

A CLINICAL meeting of the Brighton Division of the British Medical Association was held at the Royal Alexandra Hospital for Children on April 23rd, when Mr. G. MORGAN, consulting surgeon to the hospital, was in the chair.

#### INTUSSUSCEPTION.

Mr. J. R. GRIFFITH read a short paper on intussusception. The majority of cases of this disease occurred in children under 2; the patient was usually a boy, and was healthy and robust. As a rule the diagnosis was unmistakable. The attack came on suddenly, often after an attack of diarrhoea; it began with agonizing colic, the bowels emptied themselves and the patient vomited, the legs were drawn up, and the breath came in little gasping cries. The spasm passed off and was repeated. Blood-stained mucus began to drain from the rectum, and the spasms became more and more frequent until the pain became continuous. On examination a sausage-shaped swelling was detected, lying across the abdomen above the umbilicus; sometimes the apex could be felt on rectal examination. All cases, however, did not conform to this type, and sometimes it was by no means easy to make a diagnosis. It was not uncommon to find the child sleeping peacefully, with nothing but the history to suggest that there was anything wrong. The lump might appear to be absent at one time, although it was clearly evident both before and after. Occasionally no history could be obtained of the passage of blood and mucus; in these cases there was no congestion, and the intussusception was easily reduced. Operation directed towards the complete reduction of the intussusception was the only rational form of treatment, and it must be performed at the earliest possible moment, before congestion was followed by loss of vitality. Therefore, where any question of intussusception arose the child was always examined under an anaesthetic on the operating table. An abdominal and a rectal examination made it easy to decide whether the abdomen should be opened or not. With regard to the operation, a right paramedian incision was used; the intussusception was reduced as far as possible inside the abdomen, the last part being always delivered in order to make sure that it was completely reduced. This was sometimes difficult owing to thickening and oedema of the apex, but unless reduction was complete the condition would almost inevitably recur. In the case of gangrene of the bowel resection appeared to be hardly ever successful.

In the discussion which followed Mr. G. MORGAN called attention to the rise of temperature which usually followed these operations; this was due, in his opinion, to the absorption of toxins liberated from the congested bowel on the relief of the obstruction. Mr. L. A. PARRY then described a case in which pain was completely absent throughout the attack. After much doubt and discussion the abdomen was opened, the intussusception was found and reduced, and the child recovered. Mr. M. FIRZMAURICE-KELLY described two unusual cases under his care during the past year; in both the apex was formed by an inverted Meckel's diverticulum.

#### MISCELLANEOUS CASES.

Mr. M. FIRZMAURICE-KELLY showed three cases:

1. A case of old tuberculous disease of both hip-joints and the left knee in a girl aged 13. The case had been shown at a previous meeting; the left hip and knee were then fixed in good position, the right hip dislocated, and the limb flexed and adducted 50 degrees. An arthroplasty of the right hip by Jones's method was performed, and the limb was now straight, with some 30 degrees of movement in the direction of flexion. It was hoped shortly to start the child walking in a caliper splint.

2. A case of incisional hernia of the right semilunar line, 4 in. by 1 in., closed by Gallie and Le Mesurier's method, two strips of fascia lata a foot long and 1/4 in. wide being used to close the opening. The resulting scar was firm.

3. A case of obstetrical paralysis in an infant, treated on a platform splint.

Dr. W. BROADBENT showed two cases:

1. A . . . . . gangrene of the arm and leg in a child, . . . . . of both limbs.
2. A . . . . . which was cured by the administration of pancreatic extract.

Dr. FLORENCE M. EDMONDS showed a case of Schlatter's disease, cured with no special treatment beyond the avoidance of excessive exercise.

### ASSAM BRANCH.

#### TREATMENT OF LEPROSY BY METALLIC SALTS.

At the annual meeting at Jorhaut of the Assam Branch of the British Medical Association on March 2nd Colonel F. J. PALMER delivered an address on the treatment of leprosy by metallic salts.

Colonel Palmer began by stating that in Ceylon and South Africa the value of echaumogria oil and its derivatives had been somewhat discounted, whilst in Muir's most recent statement of the question there was not cited, he believed, one single case of the cure of advanced leprosy. The interpretation of the results of treatment in leprosy was more difficult than in any other condition, except the ferment treatment of cancer. Some eighteen months previously Colonel Palmer had given copper sulphate for some weeks in daily half-grain doses, by the mouth, to a patient with leprosy of the hand and a very swollen finger. The patient then disappeared for some months; he was subsequently found to have improved very much. In another case of a leprosy ulcer over the patella, with the bone exposed, the patient improved rapidly under the oral administration of copper sulphate in daily half-grain doses, and eventually returned to work, the ulcer having completely healed. The treatment was continued in periods of three weeks at a time with intermissions of a week or fortnight, and focal reactions were observed to follow the doses. Other salts of copper were then tried and other routes of administration. For intravenous use a combination of copper sulphate with sodium citrate was found most useful, and copper citrate was also found the most suitable salt for intramuscular injection. In addition to reactions in leprosy sores, after-treatment reactions might occur in places which were not apparently the site of leprosy infections. Colonel Palmer thought these might be due to (1) reactions occurring in lesions so small as to have eluded observation; (2) the toxin being liberated from dead and degenerated bacilli and acting on nerve fibres running to certain skin areas; (3) reactions appearing in elusive areas of infiltration in the tissues along the course of nerves supplying the affected areas. He preferred the first and third explanations, and considered that such reactions illustrated the widespread invasion of the body tissues by leprosy. This disease seemed to be one of low infectivity and extreme chronicity, many patients showing a high degree of resistance to it. Scars of former ulcerations sometimes reacted to treatment, suggesting that the bacilli remained alive but dormant in the cicatricial tissue. The action of copper citrate had been studied by him for nine months, and that of bismuth tartrate for three months. The former was given intravenously in fortnightly doses of  $1\frac{1}{2}$  grains; the latter, also intravenously, in 2-grain doses fortnightly. No such loss of effect was noted after repeated doses, as in the case of antimony salts. No untoward incident had resulted from these injections, no evidence of optic atrophy being obtained, though two cases of transient jaundice had occurred. No albuminuria had followed the copper treatment, but there had appeared a temporary trace of albumin in the urine of one patient under bismuth, and this metal had also produced soreness of the mouth and teeth. A slight febrile reaction seemed to follow most injections and might persist for some days.

Focal reactions were most readily produced in the following order: (1) areas already tending to break down; (2) surface infiltrations of the skin; (3) old infiltrated areas, or those below a nerve lesion; (4) deeper infiltrations of the skin; (5) an old firm white scar in a well vascularized region. In such areas the scanty dormant bacilli had been walled in by a natural protective reaction, and the cicatricial barrier probably offered great resistance to the action of substances in the blood. Early nodular cases were the

most amenable to treatment, and cases with extensive infiltration of the feet and legs the least so. No attempt had been made to reinforce the action of these drugs by diet or by dressing the sores. Colonel Palmer then referred to an article by Professor Philippo Rho in the *Journal of Tropical Medicine and Hygiene* for December 1st, 1924, on the effect of cyanide compounds of copper, which tended to confirm his own observations. He also gave clinical details of the treatment of eight patients, and his final conclusions were as follows: (1) that copper and bismuth salts were two of the most powerful agents yet introduced for the treatment of leprosy; (2) that these salts were very inexpensive at present; (3) that they both produced focal reactions in leprotic tissues, earlier or later, according to frequency and dosage; (4) that such reactions appeared to be curative, and that even advanced cases had improved so as to justify the hope that final cure was not far off; (5) that with increasing knowledge speeding up might be possible; (6) that cure could only occur through a series of reactions, which might be severe in advanced cases and make the patient appear to be worse temporarily; (7) that the potentialities of the oral administration of copper, and to a less degree of those of intramuscular bismuth, were worthy of trial.

## Reports of Societies.

### MODIFICATION OF COW'S MILK IN INFANT FEEDING.

At a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine on April 24th, the President, Dr. H. C. CAMERON, in the chair, Dr. LEONARD FINDLAY opened a discussion of the question whether modification of cow's milk was necessary in infant feeding.

Dr. Findlay, referring to the generality of infants, had no hesitation in answering the question with a negative, unless boiling was considered as a modification. He thought that raw milk ran so many risks of contamination that this danger should not be inflicted on children under 5 years, and pointed out that the ideal—a perfectly clean milk—was economically impossible of attainment. In America, recently, five cases of bovine tuberculosis had occurred in infants fed entirely on grade A milk from a most reputable dairy. Boiled milk had the advantage of being more digestible than raw milk, and only lacked the antiscorbutic vitamin, which could easily be added. In pathological states, such as fat intolerance, some modification of cow's milk was necessary, but for the average infant Dr. Findlay maintained that whole cow's milk was the best substitute for breast milk. The difference in composition between human and cow's milk would seem at the first glance to warrant modification, and the chief discrepancy was that between the two protein figures. Protein was always dependent for its action upon its constituent amino-acids. The intramolecular composition of the amino-acids of different proteins varied so greatly that an effective modification was impossible in the present state of our knowledge. Secondly, there was proof available that children were well able to digest whole milk; experiments on their metabolic balance had demonstrated this satisfactorily. There was, moreover, no evidence that a marasmic infant was less able to thrive on whole cow's milk than a normally nourished infant. Dr. Findlay had fed infants on diluted milk, peptonized milk, and citrated milk, but had always returned to the use of unmodified cow's milk. The vast majority of infants thrive on a diet of whole cow's milk. He therefore felt that the modification of cow's milk was uncalled for, except in certain pathological states, and possibly occasionally for infants under 3 weeks old.

Dr. ERIC PRITCHARD maintained that the modification of cow's milk was an absolute physiological necessity. Breast milk was the most perfect assemblage of the elements of nutrition, but in cow's milk these elements were in different proportions. The milk of various mammals differed

in metabolic properties, and the substitution of one by another was, therefore, a matter of some moment. Recent research in biochemistry had shown that there was an optimum requirement of each element; breast milk contained thirty such elements. Although the infant's stomach had great powers of adaptation and a very high degree of tolerance, yet the closer the composition of a food attained to the optimum the better would be the results obtained. The problem was difficult, and could not be met by administering undiluted cow's milk. Of the methods of modification in use at present the calorific basis of calculation did not entirely meet the case, because the biochemical reactions, hormones, and other imponderable molecular units were not considered. The percentage method of modification was open to the objection that only three of the thirty elements in breast milk were considered, the remaining twenty-seven being entirely ignored. These elements were present in cow's milk, but not in quantities representing the optimum. The calf grew at three times the rate of the infant, whilst the ratio of protein in cow's milk to that in human milk was two to three times as great. The carbohydrate in the calf's diet was supplemented by the grass it ate—a fact frequently overlooked. The protein ration necessary for adults was a matter of controversy, but it was possible to find an optimum ratio for infants. That cow's milk was less digestible than human was surely an argument for substitution, not for the feeding of the indigestible protein in excess, as was the case when whole milk was given. In apparent support of Dr. Findlay's argument was the fact that in diluting the protein the other important elements were diluted also, such as iodine, ionic calcium, iron, lecithin, cholesterol, and water-soluble vitamins, but Dr. Pritchard believed that this was an argument in favour of more scientific modification of milk. Children fed on whole milk survived because of their great power of adaptability, but there was no doubt a considerable hypertrophy of the stomach in such cases. It had recently been found that the pH for optimum gastric digestion should be 5; whole cow's milk required five times as much gastric juice to produce this figure as did breast milk. This fact explained the resultant hypertrophy of the stomach found in infants fed on whole milk. Dr. Pritchard had modified cow's milk by acidifying it with hydrochloric or lactic acid with successful results. It had been admitted even by Dr. Findlay that for some ailing babies some modification was necessary. It was Dr. Pritchard's contention that research in biochemistry should not be ignored, and that those who habitually modified milk for normal children would have greater facility and resources in dealing with ailing children.

Dr. HUGH THURSFIELD said that the doctor was expected to know the answer to the question—What, failing breast milk, was the optimum food for infants? It had been found from repeated analyses of breast milk that the average differed notably from the extremes, not only in different women, but in the same woman from day to day, and even from hour to hour. Could breast milk then be taken as a standard in modifying other milks? Clinical experience had also shown that the so-called humanized milk had not been so successful as had been expected. In order to have some idea as to what food healthy infants did thrive upon, Dr. Thurfieid had made inquiries about the children in the surgical ward in the Hospital for Sick Children who looked healthy; he was informed that the children were fed upon the same diet as they had had before admission. Their fitness for operation had been achieved by adherence to their previous diet, however far this might have departed from theoretical dietetic standards. It was certainly worthy of note that, provided an infant was healthy, it did not seem to matter very much what diet it was given. The power of adaptation was great, and the body had the ability of getting rid of unnecessary substances. He had found that children deprived of breast milk took unmodified boiled cow's milk, protected by an antiscorbutic, with enjoyment, and digested it well. The advice of London consultants was most frequently asked for children already ailing from some cause, or other; apart from infections, this want of health was most generally caused by disproportions in the feeding. It

thus became a necessary part of the treatment to modify the food with regard to the particular constituent at fault in the previous diet. It was generally believed by the laity that there was some optimum food for infants which should be defined by the doctors. In his opinion there was doubtless such an optimum for each individual infant, but the average best at present attainable was represented by boiled cow's milk for the generality of healthy infants.

Dr. R. C. JEWESBURY believed that it was absolutely essential to modify cow's milk, taking the average constitution of breast milk as the standard. He considered that there was very little variation in the composition of breast milk if the breasts were completely emptied on each occasion. The method of percentage feeding on this basis, started by Sir Frederick Truby King in New Zealand, and used by himself and others in this country, had given every success. Dr. Jewesbury showed charts of the weight curves of infants who were much below normal until they were fed on a percentage modification of cow's milk, when they immediately began to gain and rapidly reached the normal curve.

THE PRESIDENT remarked that it was in the nature of infants to grow and wax strong, and therefore great care should be exercised before accepting growth as a direct result of any particular diet. There might be said to be two schools of thought—those who started out with a foodstuff, and those who started with the infant's reaction to a foodstuff. Any modification could be regarded as a starting point from which to obtain information as to the reaction of the infant. To fix the best starting point should be the aim of clinicians. A certain number of infants would react badly to any modification. Advance could only be made by all investigators giving clear clinical pictures of the results. In his opinion infants fed on whole boiled milk were more stable than those fed on modified milks, though the latter might show more rapid growth. There were so many factors to be considered that they must recognize that no diet would ever confer health on all ailing babies.

THE sixth meeting of the Chelsea Clinical Society, held at St. George's Hospital on April 22nd, with Dr. Gordon LANE (President) in the chair, was devoted to the discussion of certain cases exhibited. Mr. B. WHITCHURCH HOWELL showed a case of malunited tibia and the excellent results obtained by simple subperiosteal resection. Mr. LAWRENCE ABEL showed a case of familial exostosis of the upper dorsal vertebrae. He also gave the history of a case of bilateral osteomyelitis of both tibiae, in which antilysin A had done much good. Dr. A. C. D. FIRTH exhibited a case of splenic enlargement associated with an increase in size of the liver; two cases of hypothyroidism, in one of which good results had been obtained with small doses of thyroid extract administered over a long period of time. He also showed a case of aortic disease with a Flint's murmur. The PRESIDENT demonstrated a case of acromegaly. Mr. ABEL showed, for Mr. P. P. COLE, a case of bony tumour of the breast, a recurrent lipoma, and a case of lipoma followed by a sarcoma. Dr. J. D. ROLLESTON concluded a most interesting evening with an exhibition of photographs of the rash of smallpox in various stages.

At a meeting of the Devon and Exeter Medico-Chirurgical Society held on April 23rd, the President, Dr. E. J. TOYE, in the chair, Dr. W. GORDON showed two cases of diabetes. (1) In a married woman, aged 37, insulin treatment had been beneficial, but when Dr. Gordon later substituted raw pancreas for the insulin he had obtained equally good results. During intervals when the insulin or raw pancreas had been omitted the glycosuria and acetonuria returned. (2) In a boy, aged 11, glycosuria and acetonuria had disappeared after dieting alone; at no time had it been necessary to give insulin. Mr. R. WAYLAND SMITH read notes on and showed a case of fracture of the femur in a middle-aged man in whom there had been considerable overlapping of fragments and replacement had been very difficult. He had plated the fragments and made use of an anterior root by splitting the crurae. The operation had proved most successful, and in addition to the extension splint a self-exercising apparatus had been arranged so that the man, by means of pulleys, could constantly flex and extend the knee-joint. Mr. Wayland Smith also showed a case of tuberculosis of the caecum; the caecum and eight inches of ileum had been removed, and after a temporary "light up" in the chest the man was now progressing favourably as a

balcony patient. Mr. NORMAN LOCK showed a boy with a deep ulcer over the tibia, eight inches in length. The Carrel-Dakin method and treatment with nitric acid and vaccines had proved of no avail, but he was at last improving under ultra-violet ray treatment. *B. pyocyaneus* had been isolated from the ulcer. Dr. F. A. ROPER showed a case of tabes dorsalis with Charcot knee-joints; the left knee-joint had enlarged rapidly, and now presented an enormous deformity. The treatment was discussed, but apart from antisyphilitic therapy—already tried over a long period—the only suggestion offered was ionization. Mr. NORMAN LOCK, with Dr. MILLER MUIR, showed a girl, aged 6, who had had an inoperable spindle-celled sarcoma in the left side of the neck. After treatment with x rays the tumour had completely disappeared, leaving only a scar over the sterno-mastoid. The treatment commenced fifteen months ago, and Dr. Miller Muir had first tried radium without success; steady and slow doses of x rays had been of more value than the intensive treatment. Dr. R. SOLLY read notes on a case of bilharziasis, apparently contracted in Mesopotamia. He described the life-history of the parasite and showed slides prepared from the urine of the patient illustrating the ova and the release of the embryo.

## Reviews.

### COMPARATIVE PHYSIOLOGY.

Is the thoughtful and interesting book to which they have given the title *An Introduction to Recent Advances in Comparative Physiology*? Dr. HOGREN and Mr. WINTER have dealt in a clear and pleasing style with a diversity of subjects, such as the fertilization of the egg, the development of the individual, the sources of vital energy, co-ordination, behaviour in animals, hereditary transmission, the material basis of inheritance, and the determination of sex. Other subjects of no less interest might be added to this list, such as the blood and circulatory and respiratory functions, the biological action of light and pigment, the production of light by living organisms, the swim bladder and its relation to audition and sense of position and equilibrium. A second volume might deal with such, and would be welcome.

While the attempt by Loeb and others to produce parthenogenesis or virgin birth by experimental means has been crowned with success, we are, say the authors, only on the threshold of a solution of the problem. One factor is proved to be the withdrawal of water from the egg. In dealing with the natural process of fertilization they point out that the sperm, when shed, becomes active in the presence of a certain degree of alkalinity and that there is a specific attraction emanating from the egg. This attraction is 100 per cent. less in the case of the sperm and eggs of hermaphrodites, and thus self-fertilization is very rare. The influence of egg extracts on the sperm is specific but not entirely so; it is destroyed by heating above 95° C.

In discussing development of the individual the authors produce evidence that bodily organization may be profoundly altered by external agencies; thus, the vestigial eyes of the blind cave salamander develop to normal size when the young are reared in red light, and monsters can be produced by acting on embryos with certain concentrations of various salts, by ultra-violet rays, etc. Strange varieties of goldfish are produced thus. Of paramount importance in the production of monsters are initial quantitative differences in cell activity. Susceptibility to external influences varies directly as the rate of metabolism in the parts of an embryo; larvae of a marine worm can be made small-headed by the early action of a cyanide salt and big-headed by the late action. The modern standpoint regards individuation, not as the outcome of a differential distribution of the hereditary determinants through cell division to different regions, but as a result of the reaction to external or internal environment. Thus in the development of the eye the retina is formed from the optic cup, an outgrowth of the brain, and the lens from the skin; if the optic cup is removed in a tadpole no lens develops, while if the optic cup is there any part of the skin grafted over it will form a lens.

The authors point to the fundamental fact that a considerable part in determining the condition of the individual is played by the presence or absence of stimuli which induce functional activity; for example, if fluid be introduced at considerable pressure into a dog's bladder the walls become thicker, simulate in microscopical structure the heart, and pulsate rhythmically at a rate of two hundred a minute.

The well known function of the thyroid in controlling the metamorphosis of tadpoles is of great interest in connexion with cretinism. Tadpoles fed on thyroid or given iodine metamorphose quickly into frogs which are the size of flies, while those deprived of their rudimentary thyroid or fed on any iodine-free diet lack the power to undergo metamorphosis. In tadpoles the rudiment of the pituitary gland is very accessible just above the mouth and can easily be destroyed. When this is done development of the thyroid is arrested and there is failure to metamorphose. Pituitary grafting, on the other hand, accelerates growth and metamorphosis in tadpoles. Thus is the uncertain evidence derived from very difficult experiments on mammals elucidated by comparative physiology. Another interesting example of this enlightenment is the discovery that while the banana fly can live and multiply on a suitable solution of salts, sugar, ammonium tartrate, and citric acid, it is necessary that its gut should teem with yeast. The yeast grows on the solution and the fly larvae obtain vitamins from the yeast and their nitrogen supply from the nucleoproteins of the yeast. Again, both larvae of blow-flies and a pulp made therefrom have, like the liver of mammals, power to split peptone into amino-acids, deaminate them with evolution of ammonia, and then with evolution of carbon dioxide produce higher fatty acids by synthesis of the deaminized acids.

Very interesting also are the authors' researches, which show that a minute dose of extract of the posterior lobe of the pituitary on injection darkens the skin of frogs by expanding the melanophores. Removal of the pituitary from the frog or salamander prevents darkening in response to light surroundings.

Enough has been said to show the nature of the discoveries which this book brings together.

### THE BACTERIOLOGY OF FOOD.

THE origin and development of bacteriology is one of the wonders of modern science, and a remarkably comprehensive sketch of it forms the introduction to a book by Dr. CUTHBERT DUKES on *The Bacteriology of Food*.<sup>2</sup> He shows how, beginning with Pasteur's discoveries, scientists started to study the microbes responsible for various industrial fermentations; how the enunciation of the germ theory of disease impelled research in a new direction; how pathogenic microbes began to be identified, and new methods of disease prevention and treatment devised; how, apart from medicine, the value became appreciated of knowledge of the microscopic world in many human activities, including agriculture and dairying; and how the biologist has made methodical survey of this new province of life. But the study of bacteriology has been so absorbing and intensive in each of its several departments that the worker in one field has scarcely found time to look over the hedge to see what was being done in the next. Medical and agricultural bacteriologists, for example, are insufficiently acquainted with each other's work. A common meeting ground may be found in the domain of hygiene and public health, which includes not merely the examination of water and milk, but all that relates to food supply, food preservation, and food decomposition. Dr. Dukes puts before the reader information from the writings of workers approaching the subject from the various points of view—medicine, hygiene, agriculture, and industry in general.

In successive chapters he deals with the bacteriology of food preservation, water, milk, butter, cheese, canned foods, alcoholic beverages, and fermented foods. The last chapter is devoted to bacterial food poisoning, which is treated under two main headings—the Gaertner group and botulism. In introducing this subject Dr. Dukes comments on the

<sup>1</sup> *An Introduction to Recent Advances in Comparative Physiology*, By Lancelot Hogren, M.A.Cantab., D.Sc.Lond., F.R.S.Edin., and Frank R. Winter, M.A.Cantab. London: W. Collins and Co., Ltd. 1925. (Med. Rev., pp. vii + 212; 29 figures. 25s. net.)

<sup>2</sup> *The Bacteriology of Food*, By Cuthbert Dukes, M.D., M.Sc., D.P.H. London: H. K. Lewis and Co., Ltd. 1925. (Demy 8vo, pp. x + 160; 25 figures. 7s. 6d. net.)

misconceptions which have arisen and still persist in the popular mind regarding the part played by ptomaines. These chemical substances are often present in putrefying meat and are highly poisonous when injected into animals, but seldom or never are they formed save when putrefaction is far advanced and the food altogether repulsive. Even if putrefying food is swallowed there is very little evidence that the ptomaines are then poisonous, for, like other organic toxic substances, such as snake venom and tetanus toxin, the poison is not absorbed by the digestive system. The ptomaino tradition, Dr. Duker complains, hampers the progress of knowledge of food poisoning, for in almost every outbreak "the magistrate, coroner, and press rest satisfied with the familiar doctrine of ptomaines, whilst valuable time is lost and the living menace remains undetected." He insists, moreover, that the bacteria which cause food poisoning are a special group altogether separate from those that form ptomaines, and from the common agents of putrefaction. Following these preliminary observations, the author proceeds to discuss the Gaertner type of bacilli, and the *Bacillus botulinus*. He places the former in a group to which many other pathogenic bacteria belong, including the *Bacillus paratyphosus* A, B, and C, whilst in addition to the Gaertner group itself there is also a para-Gaertner group.

We trust we have sufficiently indicated the contents of Dr. Duker's volume to inform our readers of its scope and assure them of its value. It is written forcibly and concisely, and in brief space gives important information and sets forth clear views with which every health officer ought to be acquainted.

#### MOTHCRAFT.

THE fifth edition of the popular manual *Mothercraft*,<sup>3</sup> which is published by the National League for Health, Maternity, and Child Welfare, has been revised and enlarged. It consists of a selection of papers from various courses of lectures on infant care given under the auspices of the National Association for the Prevention of Infant Mortality by authorities on the subjects. Dr. Still introduces the volume with a quotation from Plato that "of all animals the most difficult to manage is a child," and reviews the history of the interest shown by civilized mankind in the welfare of children. The slowly dawning realization that mother instinct must be supplemented by mothercraft is developing into a conscious demand for knowledge in the minds of many thousands of mothers. Some special attention was given in the earlier half of the seventeenth century to the study of the child in sickness, but it has taken three centuries to bring home the truth that through a fuller knowledge of disease means of prevention are to be sought and found.

It is not possible to give the names of all the distinguished persons who have contributed papers. It must suffice to say that briefly, but very helpfully, the story of the care of the child is given in counsels of attainable perfection. Beginning with ante-natal care, which in reality dates back to the adolescent, the respective articles deal with pregnancy and childbirth, reference being made to syphilis in connexion with these periods. Other articles discuss the care of the newborn infant, breast-feeding, artificial feeding, and weaning. Then the care of the developing child is dealt with, including its food and clothing, with reference in special articles to the backward and nervous child. Separate articles are given to simple ailments, dental defects, skin troubles, care of nose, throat, ear, and eyes. Respiratory diseases and, more particularly, tuberculosis in mother and infant, are described. A final article on the law relating to maternity and child welfare is helpful and instructive.

The whole gives an illuminating exhibition of the state of preventive knowledge to-day. There are many gaps in this knowledge and much ignorance remains to be dispelled, but prevention is the watchword of the child welfare movement. The exceptional value of this little manual lies in this—that it contains the collective advice of many, distinguished in the profession, instead of the views of only one author.

<sup>3</sup> *Mothercraft*. Fifth edition, revised and enlarged. London: The National League for Health, Maternity, and Child Welfare. 1925. (Cr. 8vo, pp. xvi + 400; 5 figures. 4s. 6d., post free.)

#### EAR, NOSE, AND THROAT.

IN a volume recently published in Paris, Dr. G. DE PARREL<sup>4</sup> has collected a series of articles designed to bring certain recent advances in otology and laryngology to the notice of the general practitioner. No attempt is made at a complete exposition of these special subjects such as might be found in a textbook. Certain topics on the borderland are discussed in a helpful manner, and an attempt made to bring them into touch with general medicine. One of the most interesting and informative chapters is that dealing with congenital syphilis as it affects the head and neck.

As the author has only touched on certain topics apparently selected at random, the book cannot be used for reference; moreover, much that it contains is debatable and probably ephemeral, but many fresh ideas and novel suggestions are advanced, so that it may be read with profit by the practitioner and the laryngologist. The merit of the book lies in a certain breadth of vision, but much that is commonplace might have been omitted. The author certainly helps to avoid "myopic clinique," against which he warns the specialists.

The first edition of the *Manual of Diseases of the Nose, Throat, and Ear*, by Dr. GLEASON, appeared in 1907; the edition before us is the fifth,<sup>5</sup> and the book has been many times reprinted in the intervals between the various editions, so that its popularity is evident. It presents an account of laryngology, rhinology, and otology within the compass of a single volume of moderate size. The conditions commonly met are fully discussed, the appropriate treatment set out, and the lesser operations described. The attempt to bring the book up to date, however, is not entirely successful; this is a difficulty which becomes more pronounced with each successive edition of any textbook, unless, indeed, it be entirely rewritten. Nevertheless, this book remains a safe and useful guide to the student and practitioner in the recognition and simple treatment of ordinary diseases, but it does not now meet the requirements of the specialist in any of the three branches.

The third edition of GRÜNWARD's textbook of diseases of the larynx<sup>6</sup> is one of the series of Lehmann's medical atlases. The first part of the text, which is in German, describes methods of examining the larynx, and the second part the pathology and treatment of its diseases. The great feature of the work is the coloured plates, which include histology and morbid anatomy as well as laryngoscopy.

#### AN OUTLINE OF ENDOCRINOLOGY.

BIG books on endocrinology have been fairly common recently, but smaller less numerous. Dr. W. M. CROFTON's *Outline of Endocrinology*<sup>7</sup> belongs to the latter class. In 120 pages he deals, chapter by chapter, with the functions of the pineal, pituitary, suprarenal, thyroid, parathyroid, and thymus glands, the hormones of the gastro-intestinal tract, and the pancreas. His general scheme is to pass from the histology to the development, physiology, pathology, and therapeutics of each gland. In the fields of endocrinology there is plenty of room for difference of opinion, and we do not wish to dispute the stand which Dr. Crofton takes on many controversial questions, but merely remark that time may or may not justify his dogmatism. Since he wrote primarily for medical students he had naturally to be brief; but we think that the book would have been more useful if the author had added references to larger books and original articles, in order to direct the reader to places where he could consult other opinions or find a more exhaustive presentation of those Dr. Crofton proclaims.

## A TEXTBOOK OF HISTOLOGY.

ONE of the chief merits of Professor Jordan's *Text-book of Histology*<sup>1</sup> is that it is written by one who is actively engaged in teaching that subject. As a teacher, he knows that if an interest in the subject be aroused, the student will assimilate even the dry facts of a science much more rapidly and perfectly than if his interest had not been thus awakened. Professor Jordan, therefore, gives throughout the book short accounts of the functions or physiological meaning of the tissues under discussion. Hence we find the physico-chemical theory of muscular contraction, the myogenic view of the heart beat, the mechanism of the expulsion of the ovum, and so on. After all, when the tissues are being studied is the time to be told what they do. Doubtless, to achieve the same end—interest in the meaning of structural differentiation—we are given certain most useful classifications, as, for instance, of end-organs according to Sir Charles Sherrington's terminology.

Almost all the figures, as should be the case in a manual of histology, are exceedingly clear. Only one (on page 617) teaches nothing. Some of the illustrations are of sections not found in every textbook, such as the lacrymal glands, the ceruminous glands, the glands of Bartholin, the vagina, the gall bladder, the regenerating hair, the external auditory meatus, and the pericardium.

The liver is dealt with very successfully; we do not remember to have seen such illuminating diagrams as those given here; the same is true of the treatment of neuroglia. The valuable new mounting medium, euparal, is described; sections can pass direct from 95 per cent. alcohol into it. This saves time and money, and is less trying to the undergraduate patience than the full dehydration and clarification processes for Canada balsam; further, euparal displays cytological details better than balsam. We miss a vertical section of the placenta to show the relations of the chorion to the maternal sinuses. A transverse section of the chorionic villi is given (Fig. 470); but unless the student sees also a vertical section of the placenta he will get no correct picture of this difficult organ. The manner in which the histology of the thrombocytes is dealt with is inadequate. In describing the Berlin blue injection mass, it would have been well to point out that its colour is apt to fade in the smaller vessels owing to the still living tissues acting on the pigment like a reducing agent in an alkaline medium; hence there must be a trace of acid in the mass. The omission of the names of Banting and Macleod from the allusion to insulin is quite inexplicable. The expression "heart of beef" (p. 102) is incorrect when ox or cow is meant, as "beef" means only the flesh of these animals prepared for the table.

## NOTES ON BOOKS.

THE new volume of *The Westminster Hospital Reports*<sup>2</sup> is edited by Mr. ROCK CARLING and Dr. HILDRED CARLILL. The last volume of the series was issued ten years ago; publication has been resumed at a propitious moment, for it coincides with the reopening of the hospital after extensive alterations and improvements. Nearly half the volume is given to Mr. W. G. Spencer's interesting history of the hospital, which was noticed in a previous issue of the columns on December 6th last (p. 877).

The reports of the medical and surgical registrars are given to the reports of the medical and surgical registrars and to short notes by Dr. J. A. Braxton Hicks (pathologist) on the work of that department during the years 1913-22, and an analysis of cases treated in the department for venereal disease since the beginning of the Ministry of Health scheme in 1917. For the intervening pages an ambitious scheme had been framed; the editors hoped to secure the co-operation of all the members of the staff in a systematic study of the cases. Their hopes were not fulfilled, but the contributions of this nature were with diseases of the month

and tongue, gastric and duodenal ulcer, lung complications after surgical anaesthesia, with cases coming under the jurisdiction of H.M. coroners, etc., with toxæmias of pregnancy, and with pulmonary embolism, the last being by one of the editors, Mr. Rock Carling; the other editor, Dr. Hildred Carlill, contributes a paper on tabes dorsalis, which includes a note on treatment.

*International Clinics*<sup>3</sup> is a quarterly volume of clinical lectures and original articles on different branches of medicine written by "leading members of the medical profession throughout the world." Of the twenty-six contributors to Volume IV, twenty-four are from the New World; the Old is only represented by one writer from Scotland and one from France. The contents are divided into six sections, dealing successively with the diagnosis and treatment of certain diseases, such as pellagra and Vincent's angina; the diagnosis and treatment of less clearly defined maladies, such as eczema and intestinal obstruction; general medicine; pediatrics; surgery; and industrial medicine. Certain of these articles, such as that by Dr. F. G. Banting on insulin, have already been read before some scientific society. We may call attention in particular to the lavishly illustrated article by Dr. Eliason and Dr. Hinton on internal fixation in fractures.

The new (third) volume of *The Lives of the Bakers*<sup>4</sup> is concerned chiefly with Colonel Charteris (1660-1732). Mr. BERESFORD CHANCELLOR says that no regular attempt has hitherto been made to write his life, and he was such an utter blackguard that it is just a question whether it was worth doing at all, or, if it was to be done, whether it ought not to have been included in a series of lives of notorious criminals; he was a bully, a swindler, a card-sharp, was twice cashiered from the army, and twice sentenced to death for rape. The second time he spent £15,000 (equal to £60,000 to-day) in fees and bribes, and was only reprieved because George II, in the then state of political opinion in Scotland, was afraid to allow a man connected with several influential families in that country to hang. The man leaning on the doorstep of the inn in the first plate of Hogarth's *Harlot's Progress* is a portrait of Charteris. It is bad luck for Philip Duke of Wharton (1698-1731) to be bound up with such a scoundrel. Wharton was freed too young from the discipline, injudicious though it was, of his distinguished father, and went off forthwith to commit every sort of folly; he had dissipated a large fortune before he was five and twenty, and died, killed by wine and women, at the age of thirty-three. But he was mad, or scatter-brained, rather than bad; he was a boy prodigy in classics, he was an effective public speaker, wrote a good English style, and made for himself friends among the greatest writers of the age. Just when he seemed to be settling down and his wife had given him a son and heir, she, contrary to his express instructions, took the boy to London, where an epidemic of small-pox prevailed; the infant contracted the disease and died. Wharton left his wife, abandoned general politics, intrigued with the Jacobites, and eventually went abroad and became an open rebel.

A *Clinical Index of Radium Therapy*, to which we referred at some length on April 4th (p. 670), has now been issued by the committee of the Radium Institute, London, in a bound volume, copies of which can, we understand, be obtained post free by members of the medical profession on application to the secretary, Mr. Thomas A. Garner, F.C.I.S., Radium Institute, 16, Riding House Street, London, W.1.

<sup>1</sup> *Text-book of Histology*. By H. E. Jordan, A.M., Ph.D. London and New York: D. Appleton and Co. 1924. (Med. 8vo, pp. xxviii + 657; 573 figures, 4 plates. 25s. net.)

<sup>2</sup> *The Westminster Hospital Reports*. Vol. 19. Edited by E. Rock Carling and Hildred Carlill. London: Henry J. Glasher. 1924. (Med. 8vo, pp. xvi + 229; illustrated. 7s. 6d. net.)

<sup>3</sup> *International Clinics*. Vol. IV. Edited by Henry W. Cattell, A.M., M.D. Philadelphia. Thirty-fourth series, 1924. London: J. B. Lippincott Company. 1924. (Med. 8vo, pp. xi + 308; illustrated. 42s. net per four volumes, issued quarterly.)

<sup>4</sup> *The Lives of the Bakers*. Vol. III. Charteris and Wharton. By E. Beresford Chancellor. London: P. Allan and Co. 1925. (Med. 8vo, pp. viii + 243; 6 plates. 10s. 6d. net.)

## PREPARATIONS AND APPLIANCES.

## An Alkaline Mineral Water.

BILINA is the name of a natural mineral water obtained at a spring in Czechoslovakia, not very far from Carlsbad. The analysis submitted shows that this water very closely resembles that of the well known Source de l'Hôpital at Vichy. It contains slightly less sodium bicarbonate, but has a small quantity of lithium bicarbonate. It has also rather more sparkle (2.3 of free carbonic acid in place of 1.0). The water is supplied in bottles in this country by the International Development Company, 4, Trafalgar Square, London, W.C.2. The water is palatable, and, as was to be expected, very closely resembles the Vichy water mentioned in taste. It is stated that great care is taken to ensure that the water is bottled at the springs at Bilina under the best hygienic conditions.

## EVIDENCE OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

At the meeting on May 4th of the Royal Commission on Lunacy and Mental Disorder, with Mr. H. P. MACMILLAN, K.C., in the chair, evidence was tendered on behalf of the Medico-Psychological Association of Great Britain and Ireland by Dr. R. H. Cole, Dr. M. A. Collins, Dr. Edwin Goodall, Dr. J. R. Lord, Sir Frederick Mott, and Dr. R. Worth. The printed Memorandum of Evidence submitted by the Association, together with three appendices, has since been published.<sup>1</sup>

Dr. COLE said that it was the view of his association that the safeguards provided by the existing Lunacy Acts against abuses and illegal detention had, on the whole, proved satisfactory, but the Acts had failed to keep pace with medical progress, especially in regard to the treatment of the initial and more curable stage of mental disorders. It was desirable that clinics for mental disorders, preferably in connexion with universities, medical schools, and general hospitals, should be established. Voluntary patients should be received in such clinics, and provision should also be made in them for the reception of non-volitional patients for a limited time without certification. These clinics should be provided and maintained by local authorities. The supervisory committee should be the subcommittee of a local statutory body, and the inspection and approval of buildings used for such clinics should be the duty of the central department. The Medico-Psychological Association also urged that mental hospitals should be encouraged to admit voluntary patients, who should be required to give seventy-two hours' notice of their desire to leave the institution. Further provision should be made for paying patients in homes where they could be received in the early stages of their disease without certification.

The association suggested that all matters of mental health should be centralized in the Board of Control, which should be designated the Board of Mental Health. The number of medical members on the Board should be increased, they should be better paid, and in making appointments of medical commissioners experience in general medicine and status in the profession should be taken into account. The management of all rate-supported institutions should be vested in one statutory committee of mental health of a local authority. Certain changes in the legal formalities were suggested. The certification of rate-aided patients should follow the same procedure—namely, the two certificates—as that of private patients. It was desirable that patients of either class should be admitted to mental hospitals under a provisional order, to take the place of the present urgency procedure for unwilling patients. This provisional order might be used, not only on the ground of urgency, but so as to provide means of temporary observation and treatment under safe conditions. It should be accompanied by a medical certificate specifying facts and reasons, and should hold good for three days, the period to be extended by twenty-eight days in suitable cases. It was undesirable that patients alleged to be of unsound mind should be removed to a workhouse before reception at a mental hospital. If an intermediate stage was necessary after the provision of clinics for incipient cases it would be better supplied by a special clinic under the management of the local authority. The association also laid it down that the protection afforded by Section 330 of the Lunacy Act, 1890, to medical practitioners should be extended to stay proceedings at an earlier stage than at present, and that practitioners should receive the same immunity as was given to witnesses in a court of law. The association also had certain amendments to suggest to the Mental Treatment Bill, 1923, should it be reintroduced.

The witnesses were next examined at length on their suggestions with regard to early treatment.

Dr. EDWIN GOODALL said that the association had been pressing for some years for a relaxation of lunacy law to permit of the more effective treatment of mental disorder in its early stages. The establishment of clinics assumed the existence of a general hospital, and to meet the need in areas remote from such a hospital it would be necessary to have a comprehensive scheme of hospital linkage such as was described by Lord Dawson in the interim report of the Consultative Council on Medical and Allied Services. The psychiatric clinic should be under the same administration as that of the general hospital, but in a building not contiguous. He favoured the plan in being at Munich and elsewhere in which the psychiatric unit was installed in a separate pavilion in its own grounds. It was not wise to have mental cases in the general wards.

The CHAIRMAN remarked that this would rule out many of the large hospitals of London, which could make no such provision of a separated building. Dr. GOODALL replied that London was a problem in itself, but in the great cities of Germany, even in Berlin, at the Charlottenburg Clinic, it had been found possible

<sup>1</sup> London: Adlard and Son and West Newman, Ltd.

to set apart a special building enclosed in its own grounds. Asked what would be the relation between the clinic and the existing asylum system, he said that there would be no relation at all, except in so far as incurable or violent cases were concerned. In his view, all early cases, whatever their nature, should be admissible to the clinic, where they would receive more intensive treatment than was usual at an asylum. A clinic would employ a much larger medical and nursing personnel in proportion to patients, and the staff would be assisted by a number of other medical men who were there for tuition and research. In this connexion he recited the extraordinarily large staff roll of the Boston Psychopathic Hospital, which had only 110 beds, but employed a large number of medical officers and laboratory workers in many different departments.

The CHAIRMAN said he had been impressed by the completeness of the staff at Boston, but it was hardly to be expected that many institutions, in this country at all events, could enjoy the same adequacy. He asked whether it would be a true description of the clinics that they were clearing-houses. Dr. GOODALL, in his reply, expressed strong objection to this title. The clinics would be institutions for the treatment and cure of patients, not corridors to the asylum. Patients would go there for six months, and if at the end of that time they were not cured their stay should be renewable for a further period.

Sir HUMPHRY ROLLESTON asked whether it was not better to send a maniacal patient to a secluded portion of a mental hospital rather than to a clinic, where his presence might have a detrimental effect on other patients. Dr. GOODALL answered that he knew this was often urged, but Professor Winckler, whose psychiatric clinic at Utrecht was probably the best in existence, had assured him that there was nothing in it. He was unable to see why such a patient should not be taken into the clinic; appropriate treatment he could be very quickly and effectively calmed down.

A long discussion ensued on the subject of "voluntary" patients.

The CHAIRMAN said that as a lawyer he had often felt considerable perplexity as to whether a person suffering from mental disorder could be said to have any volition at all. He felt that many of the cases spoken of as voluntary were not really voluntary having regard to the disturbance of will power and intelligence connoted by mental disorder. Dr. GOODALL suggested that this was one of the matters in which the medical profession might be trusted. The CHAIRMAN remarked that while that was true, he was not fond of colourable phrases, and a "voluntary mental patient" always seemed to him a contradiction in terms. Dr. GOODALL said that many of the patients had full volition, and others were "betwixt and between." The CHAIRMAN remarked that it might be a lawyer's prejudice, but it did not commend itself to his mind to give any particular value to the assent of a person who was mentally in a pathological condition. No one would propose to make valid a contract by a man in that state of mind signing away his property, and yet here it was proposed to rely upon the signature of such a man to a document which deprived him of his liberty. Dr. MENZIES pointed out that there was one class of persons who were liable to be forgotten in connexion with these clinics—namely, persons already certified in mental hospitals who developed a physical illness and required surgical or other treatment which a general hospital could afford. It was desirable that such persons should be transferred to the clinic at the general hospital for a short period without any breaking of their committal order.

The next point taken was the association's recommendation that the reception into mental hospitals should follow the same procedure in the case of private and of rate-aided patients.

Dr. COLE said that doubtless a second certificate in the one case as in the other would be an additional safeguard. Dr. COLLINS gave some figures to show that under the Act at present the great majority of persons came in under one certificate. Of the admissions to the Kent County Hospital in 1924, the number was 196; 7 were admitted as paupers in receipt of relief and 29 were admitted under two certificates as persons not under proper care and control.

The witnesses were next examined on their recommendation (already explained) for admission to mental hospitals under a "provisional order."

The CHAIRMAN suggested that such an order would attract to itself just the same stigma as certification. It was residence in the institution, not the procedure of admission, which constituted the stigma. Dr. MENZIES affirmed his belief that if a considerable proportion of admissions to mental hospitals were on a voluntary basis the distinction between a mental hospital and a general hospital would gradually pass away. Dr. LORD expressed the view that at his own asylum, if permission were given to take in voluntary patients, 50 per cent. of the inmates would be given to take in boarders within five years, and the stigma of detention would be correspondingly diminished. The CHAIRMAN was of opinion that the amount of renaming would obliterate the fact, which constituted the real stigma in the popular mind, that in a person's life there had been a "pathological episode" during which he had ceased to be to some extent a normal, rational human being. Everyone would agree that the mental hospital should be assimilated as far as possible to the general hospital as a place of hopefulness and cure. On the point that a psychiatric department in a general hospital might attract to itself something of the same stigma, one of the Commissioners mentioned that the mental ward in one institution he was aware of was known as the "barmy ward."

The examination of the witnesses had not concluded when the Commission rose for the day.

## Nova et Vetera.

### A POET'S ANATOMY.

THE metrical form has not often been used as a means of conveying exact knowledge, and anatomists and physiologists have doubtless shown a wise discretion in avoiding it. Yet it was chosen nearly three hundred years ago by the Rev. Phineas Fletcher for that purpose.

Phineas Fletcher was born in 1582, the son of a Kentish clergyman; he was educated at Eton and at King's College, Cambridge, of which he was a Scholar and a Fellow. During his residence at the university he wrote a pastoral play, *Sicelides, A Piscatory*, which was published in London in 1631, "As it hath bene Acted in King's Colledge in Cambridge." Two years later *The Purple Island* appeared, "Printed by the Printers to the Universitie of Cambridge 1633." His other poetical works and those of his younger brother Giles call for no mention here. Sir Henry Willoughby, in whose house in Derbyshire he was for five years chaplain, presented him to the living of Hilgny in Norfolk, where he married and spent the rest of his life, and where this poem was written.

Phineas must not be confused with his greater contemporary John Fletcher, the dramatist and associate of Beaumont, who was also the son of a country clergyman, a Cantab., and a native of Rye, only a few miles distant from the birthplace of Phineas at Cranbrook. It is not likely that Phineas had any practical knowledge of anatomy, but he probably had read Vesalius or one of his translators. He showed no knowledge of the recent discoveries of his countryman Harvey, although Harvey's lectures were delivered early in 1616 and the treatise *De Motu Cordis et Sanguinis* was published in 1628.

*The Purple Island, or Isle of Man*, is a pastoral poem in twelve cantos of seven-lined rhyming stanzas, in which not only is man's body and its functions described in an allegorical fashion, but the Creation and the Fall and the strife between sin and virtue and other high matters are set forth. It will readily be admitted that for so vast a subject 4,879 lines are none too many. It has been suggested that in treating the anatomy of the human body in this allegorical fashion Fletcher was merely elaborating the twelfth chapter of Ecclesiastes, but it is not certain that that chapter is wholly anatomical in its conceptions. The allegorical descriptions in the text are accompanied by copious marginal notes which purport to translate the allegorical statements of the poem into plain English.

The first canto consists of an account of the Creation and Fall of man, but in the second we come down to more prosaic matters. After stating that the bones, cartilages, and ligaments are formed respectively of different constituents of the seed, he comes to the vascular and nervous systems and then to the skin, the following description of which amply exemplifies the value of marginal notes:

"The first of these is that round spreading fence,  
Which like a sea girls th'Isle in every part;  
Of fairest building, quick and nimble sense.  
Of common matter fram'd with special art;  
Of middle temper, outwardst of all,  
To warn of every chance that may befall:  
The same a fence, and spie; a watchman and a wall."

And so on. The note to this stanza runs as follows:

"The skinne is a membrane of all the rest of the most large, and thick, formed of the mixture of seed and blood; the covering, and ornament of parts that are under it: the temper moderate, the proper organ of outward touching (say Physicians)."

After describing the fat and the walls of the abdomen he comes to the "Urino-Lake," as he calls the bladder, and to the parts of generation, which his modesty will not allow him to particularize:

"From thence with blinder passage (flying name)  
These noysome streams a secret pipe conveys;  
Which though we thide the hidden parts of shame,  
Yet for the skille deserve no lesser praise."

Elsewhere he writes:

"Flie then those parts, which best are undescried,  
Forbear my maiden song, to blazon wide  
What th'Isle and Nature's self doth ever strive to hide."

"If, as seems most probable, Phineas was the author of the anonymous but lascivious poem, "Brittain's Ida," we can understand his reluctance to acknowledge its authorship. His opinions of pregnancy and lactation are quaint. Thus in verse he sings:

"For when the lesser Island (still increasing)  
In Venus temple to some greatness swells,  
Now larger rooms and bigger spaces seizing,  
It stops the Itear rivers; backward reels  
The stream and to these hills bears up her flight,  
And in these founts (by some strange hidden might)  
Dies his fair rosie waves into a lily white."

After this the marginal prose comes with a sense of bathos thus:

"When the infant grows big he so oppresseth the vessels of blood, that partly through the readinesse of the passage, but especially by the providence of God, the blood turns back to the breast and there by an innate but wonderfull facultie is turned into milk."

Of the Diazomo or Diaphragma we are told in a note:

"Here most men have placed the seat of laughter: It hath much sympathie with the brain; so that if the midriffe be inflamed, present madness ensues it."

As is well known, the early anatomists were much impressed by the size of the liver, and, knowing practically nothing of its functions, they did not hesitate to invent a great deal.

"In this fair town, the Isles great steward dwells;  
His porphyric house glitters in purple die;  
In purple clad himself; from hence he deals  
His store to all the Isles necessitie."

The joviall hepar sits, with great expence  
Cheering the Islo by his sweet influence,  
So slakes their envious rage and endless difference."

The sufferer from long residence in the tropics will hardly recognize his tyrant in this guise.

"Within some say Love hath his habitation;  
Not Cupid's self, but Cupid's better brother:  
For Cupid's self dwells with a lower nation,  
But this more sure, much chaster than the other;  
By whose command we either love our kinde,  
Or with most perfect love affect the minde;  
With such a diamond knot he often souls can binde."

A marginal note reminds us that "hero Plato disposed his seat of love." But, unfortunately, although the liver is beneficent its excrements are not:

"Three pois'nous liquors from this purple well  
Rise with the native streams."

One is red, one black, and the third "wheyish cold." The fiery red fluid is "the spring of dire debate and civil ire," but Choleodochus or the Gall takes charge of it, "And safely locks it up in prison bands"; while "The third bad water bubbling from the fountain" goes to the Nephros mountain or kidneys, "Which suck the best for growth, and nourishment," and the worst "Runs down to the Urino-Lake, his banks thrice daily filling."

The idea expressed in the last line of the periodical excretion of urine is curious and not easily explained, except as an example of the popular liking for the number three.

If it were not for the spleen, which deals with the black fluid, we should all be in a very bad way, for as the notes explain:

"If the splene should fail in this office the whole body would be filled with melancholy fancies and vain terrors;  
"Where the splene flourishes all the body decays, and withers; where the splene is kept down, the body flourishes. Hence Stratonius merrily said that in Crete dead men walked because they were so splenitive and pale-coloured."

This is rather contradictory and puzzling, and it would seem that our reverend anatomist had not quite grasped the current pathology, but the reference to Stratonius suggests the enlarged spleen of malaria.

The stanzas on the brain and the organs of special sense merely represent the usual seventeenth century physiology, whose teachers had not yet learnt to admit how little they did know and often hid their ignorance behind a closely woven veil of speculation.

We cannot recommend *The Purple Island* as a textbook of anatomy, but Phineas Fletcher is still worth reading for his melodious verse, wealth of language, and picturesque imagery.

# British Medical Journal.

SATURDAY, MAY 9TH, 1925.

## PUERPERAL SEPSIS.

WE offer our congratulations to the members and executive of the British Congress of Obstetrics and Gynaecology on the success, both scientific and social, which has attended their meetings recently held in London, an account of the proceedings at which has appeared in our last two issues. The pooling of the professional experiences of those intimately concerned in the advance of obstetrics and in the teaching of this important branch of medicine cannot fail to have results of value, not only for the profession but for the community. In particular the discussion of the topical subject of puerperal sepsis, to which the Congress devoted its opening day, must compel the grave attention of the Ministry of Health, the Central Midwives Board, and generally of the members of the medical profession engaged in midwifery. Evidence is forthcoming, moreover, that public opinion is becoming anxiously concerned, and a note of real responsibility marked its consideration by the Congress.

Sir George Newman, in a prefatory note to Dame Janet Campbell's very able report on maternal mortality, issued by the Ministry last year, says: "The problem with which we are faced is this. There are not less than, say, 700,000 mothers in England and Wales giving birth to children per annum. Of this number approximately 3,000 per annum have died during the last ten years in the fulfilment of this maternal function. That is a serious and largely an avoidable loss of life at the time of its highest capacity and in its most fruitful effort. Yet the number of deaths by no means indicates the whole loss, for a vastly greater number than 3,000 of these mothers are permanently injured or invalided in this physiological process of childbirth." In this total maternal mortality and morbidity, thus so forcefully and justifiably deprecated, the "sepsis" factor is dominant, and, by common consent, is the most amenable to solution by way of prevention; the question naturally arises why a factor admittedly largely preventable has continued to hold so outstanding a position.

The two reports-in-chief, summaries of which were published in our issue of April 25th, were presented by the President, Dr. H. Russell Andrews, and by Dr. Daniel Dougal, both of whom had expended much time in ably analysing the material submitted to their respective committees. The President's report dealt with returns submitted through the constituent societies of the Congress other than the North of England Obstetrical and Gynaecological Society, and Dr. Dougal's with information garnered by that society. The basis material in both reports, as would be expected from their declared objective, which was the prognosis and treatment of puerperal sepsis, was mainly clinical, and incidentally bacteriological or pathological. Sir Even Maclean's paper on puerperal sepsis in Wales dealt with an interesting aspect of the problem as it meets the local authorities, the general practitioners in rural and urbanized areas, and the midwives, and further illustrated the important posi-

tion taken by the Principality in the sepsis and general maternal mortality tables. Valuable contributions to the essentially bacteriological considerations, both in evident sepsis and in pregnancy presumably normal, were contained in the joint communications of Dr. Gibbon FitzGibbon and Professor J. W. Bigger. Dr. T. H. C. Stevenson of the General Register Office emphasized by means of graphs the fact that puerperal sepsis mortality has a winter maximum in the fourth and first quarters of the year, and that this applied also to some of the "other causes" of maternal mortality in which a "sepsis" element may be assumed to exist—as, for instance, phlegmasia alba dolens. Dr. Stevenson and other speakers in the course of the discussion referred to the difficulty of making international comparisons, and the view was expressed that the need of so amending the International List of Causes of Death as to meet this point ought to be represented in the proper quarter.

The general discussion was opened by Professor J. Whitridge Williams of Baltimore, who, together with Professor W. W. Chipman of Montreal, was cordially welcomed as one of the official guests of the Congress. Dr. Whitridge Williams observed that whilst there was much obviously common ground in the two reports, the disparities were due mainly to the more serious type of cases selected for analysis by the North of England Committee. A mortality of 35.8 per cent. in 247 cases was shown in the London report, as against 76 per cent. in 154 cases in that of the North of England Society. He laid stress on the points demonstrated by both reports, points which he said he had for years been teaching in America: first, that women subjected to much manipulation were more likely to develop infection than those who were left alone; and secondly, that in infected cases intra-uterine manipulation was especially dangerous; both reports gave such cases a mortality of something like 80 per cent. He considered that the value of anti-streptococcic serum was in the balance, and he was frankly pessimistic as to the effect of treatment in severe cases of infection, particularly if associated with general streptococcic peritonitis, when death was practically inevitable. This view was combated to a certain extent by Professor Blair Bell, who claimed that some of the cases complicated by peritonitis could be saved by drainage of the peritoneal cavity. Dr. Whitridge Williams, indeed, agreed that in severe cases with pyaemia operative treatment might reduce the mortality from about 70 per cent. to 50 per cent., but maintained that cases which did not show these acute general conditions might recover if left alone, prognosis depending on the resistance of the patient and the virulence of the organisms. What was wanted, he urged, was research, not purely obstetrical, but proceeding on general lines of bacterial investigation. In commenting on the observations of Drs. FitzGibbon and Bigger, which appeared to indicate that, roughly, streptococci (fortunately not of the haemolytic type) were found in the vagina of the pregnant woman in two cases out of three, he said that the technique was, perhaps, not above suspicion, and deprecated the use of the term "endogenous infection" except in regard to the gonococcus and possibly certain saprophytic organisms. Dr. Whitridge Williams is clearly a whole-hearted supporter of the view that, with the exceptions mentioned, it is proper to regard the source of puerperal infection as exogenous. But this opinion was not shared by other speakers, and Mr. Victor Bonney restated his belief that puerperal sepsis was principally autogenetic, and

that it was making too much of the bacteriological evidence to believe that only haemolytic streptococci could give rise to sepsis.

The claim that non-haemolytic streptococci may be included in the normal vaginal or post-partum uterine flora, though not quite new, requires confirmation, and the hint of the possible existence of certain undefined conditions which may confer pathogenicity on this type of streptococcus also supports the call for further organized research. Subsequent speakers, notably Dr. C. E. Douglas (Cupar, Fife) and Lady Barrett, urged that such further research should have fuller regard to the factors which constitute and the conditions which may vary the power of resistance to infection, and this view is undoubtedly shared by many. As to treatment, reference to our reports of the discussion shows some methods recommended, but the two reports-in-chief practically agree that the various treatments mentioned in the returns represent such a medley of ways and means as to defy analysis.

The educational, the propaganda, and the administrative aspects of the subject were not forgotten, and, whenever tested, the feeling of the Congress supported those who advocated the fuller practical training in obstetrics of the medical student; the more complete and better organized provision of well trained and suitably educated midwives; the ante-natal supervision of mothers, both domiciliary and, where necessary, in clinics, as advocated by the British Medical Association in the evidence before the Royal Commission on the Insurance Acts; and a substantial addition to the existing provision of maternity homes and of maternity wards in or in connexion with the general hospitals. In regard to this last-named requirement the Congress unanimously adopted for submission to the Ministry of Health a resolution to the effect that "the most urgent requirement in connexion with the problem of puerperal sepsis is the provision of adequate accommodation for the reception and treatment of these cases in hospitals, supervised wherever possible by obstetric surgeons."

It remains to add that perhaps never before has such a degree of influential attention been focused on this principal item in the maternal mortality rate of our country. The Ministry of Health is gravely concerned, and is asking for advice and guidance in the matters of definition and notification from the Obstetrical and Gynaecological Section of the Royal Society of Medicine. The reply of the Section has been submitted to the Council of the British Medical Association, which has set up a special committee on the causation of puerperal morbidity and mortality; the reply has been referred to this committee, which will report also on the administrative action that may properly be taken in the matter through the vast machinery of the Association. It is understood that the Central Midwives Board contemplates an inquiry through the agency of the local authorities, and the Society of Medical Officers of Health and the midwives' organizations are also keenly interested.

There is already evident some danger of overlapping and dissipation of energy, and it would seem appropriate to suggest that the Minister of Health might consider the advisability of summoning a conference of representatives of the bodies and interests principally concerned, in order that the genuine interest aroused may be turned to the best account and the various parts of the whole subject allocated to persons or bodies to the best advantage, and that thus the prospect of this great problem being handled in a fashion befitting its truly national importance may be enhanced.

## CLINICAL FEATURES AND PREVENTION OF FOOD POISONING.

THE record of one hundred recent outbreaks of food poisoning in this country, which form the basis of the report of the Medical Research Council analysed elsewhere in this issue (p. 897), has two lessons to teach which deserve a special emphasis; they are included in the sections which deal with the clinical features and the prevention of food poisoning. The opinions Dr. W. G. Savage and Mr. Bruce White express on these two subjects, whether accepted in their entirety or not, are likely to conduce to the formation of a clearer idea of the clinical features of food poisoning, and to point the way to the safeguarding of food from infection.

Excluding botulism—a very deadly, and fortunately extremely rare, form of food poisoning—we find a remarkable uniformity of symptoms in all the other outbreaks reported in this country. The cardinal symptoms of the salmonella type of food poisoning are diarrhoea, vomiting, and abdominal pain. The significance of these symptoms will be appreciated if the different agencies which may be at work in this variety, much the commonest, of bacterial poisoning have been dissected out. Thus, food may be infected with living salmonella bacilli, this constituting the most serious factor. Or, as in canned food, the living germs may have been destroyed, but the toxin they formed, being more resistant to heat than the living cells, may survive in the food; this is the second and less serious element to be considered. Finally, the experimental work which Dr. Savage and Mr. White described in their earlier report on food poisoning and the salmonella group<sup>1</sup> defined the existence of a potent gastro-intestinal irritant in food so infected, and this, acting alone, accounts for the mildest type of illness.

Taking these three possibilities in the reverse order, we note that in some outbreaks of food poisoning the only symptoms are those of transient gastro-intestinal irritation, without any evidence of absorption of toxic substances. These outbreaks are characterized by a short incubation period, rapid recovery, and no troublesome sequelae. In this variety the only factor to be reckoned with is the irritant action on the alimentary tract, and probably the majority of such cases do not come to medical notice, and do not figure in their true proportion in any statistics of food poisoning. More serious symptoms result when this irritant action is followed by the absorption of the specific toxins the salmonella have formed during their growth. The main effect of these toxins is severe gastro-enteritis associated with constitutional disturbance such as fever, prostration, and cramping pains. These pass off quickly as the toxic substance is eliminated, and after twenty-four hours all anxiety has usually passed. This form of food poisoning is rarely fatal. The features which distinguish it are the rapid onset of severe symptoms, manifesting themselves in two to four hours after eating the food, and the equally rapid return to health. Statistics show that canned food is the commonest vehicle for this type of infection, a fact which is easily understood when the power of heat resistance possessed by salmonella toxin is remembered. Food poisoning in its most dangerous form follows when living salmonella bacilli are taken with the food. As toxins may also be present the incubation period may be as short as before, but the initial symptoms are followed by a severe illness which runs a protracted course. Here the patient suffers from a general bacterial infection, and we may expect several days of fever and a slow convalescence.

<sup>1</sup> Medical Research Council, Special Report No. 91.

Unfortunately, the mortality from food poisoning in this country is low, probably only about 1.2 to 1.3 per cent. even when infection with living salmonella bacilli has occurred; in outbreaks due to salmonella infections alone the mortality is about 0.54 per cent. Food poisoning of this type leads to a fatal issue usually only in patients suffering from some debilitating disease, or those already afflicted with an intestinal lesion, or patients at the extremes of life.

The ultimate goal of hygiene is the complete prevention of food poisoning. We can only advance to this step by step, but the researches of recent years have indicated a number of limited objectives well within reach. It must be recognized that food poisoning is not the result of the normal decomposition of food, but the infection of food with a special class of bacteria, the salmonellas. Not all of these need special guard, only a few are of any pathological significance. It is the essence of the problem is how to control these especially dangerous germs, and to exclude them from food supplies. To solve this question the authors of this report make three suggestions which deserve careful thought.

The first step in the control of bacteria responsible for food poisoning is more accurate knowledge of their habitat. Of this little is known, and it is unfortunate that usually outbreaks of food poisoning are inadequately studied. Thus, only a few outbreaks come under any official cognizance; even in Dr. Savage's report several only came to be investigated through the dovetailing up of paragraphs in newspapers, and were usually unknown to the official guardians of the public health, central or local. Some system of notification might, it is thought, be helpful by enabling medical officers of health to investigate outbreaks earlier and more thoroughly. Some local authorities have a skilled staff to undertake bacteriological and chemical inquiries, but others have not. All outbreaks which epidemiological inquiries suggest to be food poisoning ought to be investigated, and the investigation should include the study of *post-mortem* material. An autopsy is usually held in a fatal case, and sometimes a *post-mortem* examination is made, but to obtain the best results the services of a pathologist familiar with food poisoning should be available.

The second step in control which Dr. Savage suggests is better supervision of "made-up" foods, such as meat pies, brawn, potted meat, and sausages. They are considered to be an important class as a source of food poisoning outbreaks. The meat from which they are made undergoes considerable manipulation, and is therefore specially liable to bacterial contamination. They are mostly foods which are heated and then cooled slowly, offering an encouraging medium to bacterial growth. Their preparation is not infrequently undertaken in slaughterhouses or adjacent premises where opportunities for specific infection are plentiful. Supervision could be exercised by requiring that every person carrying on such a business should be licensed to do so by the local authority, which should satisfy itself that the premises are suitable, the procedures likely to be conducted in a cleanly fashion, and all precautions taken to prevent specific bacterial contamination.

A third step in control should be directed to diminish outbreaks of food poisoning from canned food, which is a frequent vehicle for the transmission of food poisoning, particularly that variety due to toxins of the salmonella bacilli. Since infection of the food must arise before the food is put into tins, or before these are sealed, attention must be focused on the place of manufacture. Some properly developed

system of coding, with disclosure of the code marks to a central authority in the country of import, would materially facilitate investigation of any particular consignment.

These measures would do a great deal, but, as the report observes, "any effective control is only likely to be attained when our knowledge of the parasitic and saprophytic life of the salmonella group has been put upon a basis of exactly ascertained fact."

#### INOPERABLE CARCINOMA OF THE CERVIX.

In a leading article in our issue of March 28th, 1925, reference was made to two American reports dealing with the incidence of carcinoma of the cervix uteri, and its response to radium therapy alone, or combined with x-ray treatment. In each report the conclusion was reached that the combination of radium and x rays in the treatment of this form of cancer is likely to gain favour, especially in borderline and inoperable cases; in the inoperable cases better results were obtained by radium therapy than by any other non-operative palliative procedure, or by cauterization. In his *Clinical Index of Radium Therapy*, published by the London Radium Institute, and reviewed in our issue of April 4th (p. 670), Mr. Hayward Pinch dwells on the need for forming a clear opinion as to the operability or otherwise of the growth in cervical cancer, and for relying principally in inoperable cases upon radiation, supplemented by local operations, such as excision, scraping, or diathermy, of fungating portions of the growth. In our present issue will be found a paper by Dr. Malcolm Donaldson upon the treatment of inoperable carcinoma of the cervix with radium, based in the main on his experience of 85 cases treated at St. Bartholomew's Hospital during the past four years, but taking into account also the methods and results of other workers in various centres abroad. We publish also a paper by Dr. Gilbert Strachan upon the same subject, founded on a study of 40 cases treated with radium at the Cardiff Royal Infirmary during the past three years; both papers were communicated to the fifth British Congress of Obstetrics and Gynaecology held in London a fortnight ago. In the discussion that followed Dr. Watts Eden made the significant remark that it almost seemed as though surgery had said its last word about carcinoma of the cervix; the extended operation had been carried to a point from which, he imagined, no further advance was possible; it would be necessary to look to radium alone in cases in which an operation could not be done. Again, two French workers, whose recent paper is summarized in the *Epitome* this week (paragraph 478), while sceptical about radium as a routine mode of treating cervical carcinoma, and satisfied that at present all operable cases should be treated surgically, are emphatic in declaring that, when the limits of the neoplasm cannot easily be passed in surgical extirpation, radium is preferable to all other modes of treatment. From all this, we think, the inference may legitimately be drawn that the treatment of inoperable carcinoma of the cervix uteri has now become a special branch of the cancer problem, calling for intensive inquiry along collective lines, and that the most hopeful method of treatment in such cases is either by radium or by x rays. Serious work in this direction has, however, been carried out during so short a space of time that the most suitable technique has yet to be determined. Two needs in particular suggest themselves: uniformity in the recording of observations, and employment of the same technique by each worker in a series of cases. With a view to meeting these two primary needs an informal association has been formed in this country by a number of workers in this field, in order that suggestions, methods, and published papers bearing on the subject may be circulated to all concerned. The object, as we understand it, is not to hold
